Although these bats were known thus early to Europeans, the species to which they belonged were not determined for a long time, several of the large frugivorous species having been wrongly set down as blood-suckers, and named accordingly. Thus the name *Vampyrus* was suggested to Geoffroy and adopted by Spix, who also considered that the long-tongued bats of the group *Glossophaga* were addicted to blood, and accordingly described *Glossophaga soricina* as a very cruel blood-sucker (*sanguisuga crudelissima*), believing that the long brush-tipped tongue was used to increase the flow of blood. *Vampyrus spectrum*, a large bat inhabiting Brazil, of sufficiently forbidding aspect, which was long considered by naturalists to be thoroughly sanguivorous in its habits, and named accordingly by Geoffroy, has been shown by the observations of travellers to be mainly frugivorous, and is considered by the inhabitants of the countries in which it is found to be perfectly harmless. Charles Waterton believed *Artibeus planirostris*, a common bat in British Guiana, usually found in the roofs of houses, and now known to be frugivorous, to be the veritable vampire; but neither he nor any of the naturalists that preceded him had succeeded in detecting any bat in the act of drawing blood. It fell to the lot of Charles Darwin to determine one of the blood-sucking species at least, and the following is his account of the circumstances under which the discovery of the sanguivorous habits of *Desmodus rufus* was made: "The vampire bat is often the cause of much trouble by biting the horses on their withers. The injury is generally not so much owing to the loss of blood as to the inflammation which the pressure of the saddle afterwards produces. The whole circumstance has lately been doubted in England; I was therefore fortunate in being present when one was actually caught on a horse's back. We were bivouacking late one evening near Coquimbo, in Chile, when my servant, noticing that one of the horses was very restive, went to see what was the matter, and, fancying he could detect something, suddenly put his hand on the beast's withers, and secured the vampire" (*Naturalist's Voyage Round the World*, p. 22).

Desmodus rufus, the common blood-sucking bat, is widely spread over the tropical and subtropical parts of Central and South America from Oaxaca to southern Brazil and Chile. It is a comparatively small bat, a little larger than the noctule, the head and body about 3 in. in length, the forearm $2\frac{1}{2}$, with a remarkably long and strong thumb; it is destitute of a tail, and has a very peculiar physiognomy (fig. 1). The body is covered with rather short fur of a reddish-brown colour but varying in shade, the extremities of the hairs sometimes ashy. The teeth are peculiar and characteristic, admirably adapted for the purposes for which they are employed. The upper front teeth (incisors), of which there are only two, are enormously enlarged (see fig. 2), and in shape obliquely triangular like small guillotines. The canines, though smaller than the incisors, are large and sharp; but the cheek-teeth, so well developed in other bats, are very small and reduced in number to two above and three below, on each side, with laterally compressed crowns rising but slightly above the level of the gum, their longitudinally disposed cutting edges (in the upper jaw) being continuous with the base of the canine and with each other. The lower front teeth (incisors) are small, bifid, in pairs, and separated from the canines, with a space in front. The lower cheek-teeth are narrow, like those in the upper jaw, but the anterior tooth is slightly larger than the others, and separated by a small space from the canines. Behind the lower incisors the jaw is deeply hollowed out to receive the extremities of the large upper incisors.

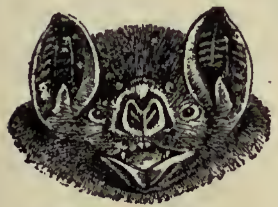

FIG. 1.—Head of Blood-sucking Vampire (*Desmodus rufus*).

With this peculiar dentition there is associated as remarkable a departure from the general type in the form of the digestive apparatus. The exceedingly narrow oesophagus opens at right angles into a narrow, intestine-like stomach, which almost immediately terminates on the right, without a distinct pylorus, in the duodenum, but on the left forms a greatly elongated caecum, bent and folded upon itself, which appears at first sight like part of the intestines. This, the cardiac extremity of the stomach, is, for a short distance to the left of the entrance of the oesophagus, still very narrow, but soon increases in size, till near its termination it attains a diameter quite three times that of the short pyloric portion. The length of this cardiac diverticulum of the stomach appears to vary from 2 to 6 in., the size in each specimen probably depending on the amount of food obtained by the animal before it was captured.

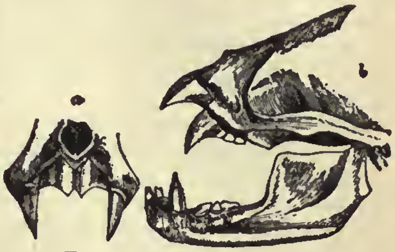

FIG. 2.—Teeth of *D. rufus*.

The only other known species of blood-sucking bat, *Diphylla ecaudata*, inhabits Brazil, and appears to be much less abundant than *Desmodus rufus*, from which it is distinguished by its slightly smaller size, by the absence of a groove in the front of the lower lip, the non-development of the interfemoral membrane in the centre, and the presence of a short calcaneum (absent in *D. rufus*), but more particularly by the presence of an additional rudimentary cheek-tooth (?molar) above and below, and the peculiar form of the lower incisors, which are much expanded in the direction of the jaws and pectinated, forming a semicircular row touching each other, the outer incisors being wider than the inner ones, with six notches, the inner incisors with three each.

Travellers describe the wounds inflicted by the large sharp-edged incisors as being similar to those caused by a razor when shaving: a portion of the skin is shaved off and, a large number of severed capillary vessels being thus exposed, a constant flow of blood is maintained. From this source the blood is drawn through the exceedingly narrow gullet—too narrow for anything solid to pass—into the intestine-like stomach, whence it is, probably, gradually drawn off during the slow progress of digestion, while the animal, sated with food, is hanging in a state of torpidity from the roof of its cave or from the inner sides of a hollow tree. (G. E. D.)

VAMPYRELLA (L. Cienkowski), a genus of azoosporous Proteomyxa (*q.v.*), parasitic on freshwater algae.

VAN. (1) The chief town of a vilayet of the same name in Asiatic Turkey; altitude, 5400 ft. Pop. 28,000, of whom 14,000 are Armenians, and the remainder Moslems, mostly of a mixed Kurdish race. It is situated about a mile from the eastern shore of Lake Van, and built along the south side of the citadel rock, an isolated rocky ridge 1300 yds. long, rising 360 ft. out of a plain which extends up to the sharply defined rocky mass of the Varak range, 8 m. distant. On the gently sloping ground east of the citadel are the Gardens, covering an area of 5 m. by 3, and containing several suburbs and detached houses, along central avenues fringed with trees, and having channels of running water by the sides for irrigation.

The town itself is a poor place with flat-roofed mud houses, narrow winding streets, and surrounded by a ruinous mud wall; but it still contains the business quarter, the government offices and the principal bazaars. In the Gardens are vineyards and orchards of apple, pear, quince, plum and apricot; the houses of the wealthier inhabitants are imposing, built of a wood-framework on a stone foundation and filled in with sun-dried bricks. Many of them are brightly ornamented in the Persian style. Water comes from *karez* or underground channels and streams from Varak, fed from the Sikhe Lake, an ancient reservoir which preserves the snow waters on the summit of the mountain. For the southern quarter there is the Shemiram Canal, also of very ancient construction, which derives its supply from a large spring 19 m. distant, near Meshingird. There are British, Russian and French consuls who reside in the Gardens. There are a large American Mission with schools, orphanage and a resident doctor, a French (Dominican) Mission with schools, and also a branch of the archbishop of Canterbury's Mission to the Nestorian Christians who live in the mountains to the south. The climate is generally healthy, extremely cold in winter, with 2 to 3 ft. of snow from December to March, while the summer heat is not excessive. The Persian trade of Van has declined; European goods, with which the bazaars are fairly well supplied, come from Trebizond through Erzerum. There is a fair local trade in wheat and agricultural produce, also sheep and cattle, wool, hides and furs for export. A thick woollen cloth called *shayak*, coarse cotton chintzes and a kind of soap prepared from the efflorescences of the lake, with dried and salted fish, are also produced.

The cuneiform inscriptions of Van are very numerous, the town having been the capital of the Vannic kingdom of the Assyrian period. At the end of the Gardens is the rocky mass of Toprak Kale, on which was a fire temple and altar; near it is the Meker Kapusi ("Door of Mithridates"), a large inscribed slab of rock with the names of several deities. On the citadel rock are several inscriptions, the principal being a trilingual one of Xerxes on the southern face. Many other inscribed stones and tablets have been found built into modern buildings, while the excavation of a mound brought to light relics of a stone age.

Van occupies the site of Dhuspas, of which the native name was Biainas (Assyrian, *Urardhu*), the Byana of Ptolemy and the Ivan of Cedrenus, whence the modern Van. Dhuspas, the Thospia of Ptolemy, gave its name to the district of Thospitis, the modern Thosp. The Biainian dynasty, of which Sarduris I. (*c.* 833 B.C.) was the first king, died out with Sarduris II., who in 645 B.C. entered into an alliance with Assur-bani-pal. Inscriptions of nearly all the kings exist, and the various excavations at Toprak Kale show an advanced state of civilization and great technical skill (see illustrations in Maspero's *Histoire ancienne*, vol. iii., *Les Empires*). In the 6th century B.C. Van passed into the hands of the Persians, and shortly before it fell to Alexander the Great it was rebuilt, according to Armenian historians, by a native prince called Van. In 149 B.C. Valarsaces or Vagharshag, the first Armenian king of the Arsacidae, rebuilt the town, and a colony of Jews was settled in it by Tigranes (94–56 B.C.). In the middle of the 4th century A.D. it was taken by Sapor (Shapur) II., and became the capital of an autonomous province of the Sassanian Empire, until it fell into the hands of the Arabs (*c.* 640), under whom it regained its autonomy. About 908 the governor of Van or Vaspuragan was crowned king by the caliph Moktadir, and in 1021 his descendant Senekherim was persuaded by Basil II. to exchange his kingdom for the viceroyalty of the Sebasteian theme. After having formed part of the possessions of the Seljuks, Mongols, Tatars and Persians, Van passed in 1514, after the defeat of Shah Ismail by Selim I. at the battle of Kalderan, to the Osmanlis, who only occupied the town in 1543. In 1636 it was taken by the Persians, but soon recovered. In 1845 the town was held for a time by the Kurd chief Khan Mahmud, who eventually surrendered and was exiled.

(2) The vilayet of Van lies along the Persian frontier between the vilayets of Erzerum and Mosul. The northern sanjak comprises open plateau country N. and E. of the lake (with a large Armenian agricultural population and Kurdish semi-nomad tribes occupied chiefly in cattle and sheep raising), also of several fertile districts along the south shore of the lake. The southern sanjak is entirely mountainous, little developed and having the tribes only partly under government control. This comprises most of the upper basin of the Great Zab, with the country of the Nestorian Christians and many districts inhabited by Kurdish tribes, some of them large nomad tribes who descend for the winter to the plains of the Tigris.

The mineral wealth of the vilayet has never been fully explored, but is believed to be great. There are petroleum springs at Kordzot, deposits of lignite at Sivan and Nurduz, several hot springs at Zilan Deresi and Julamerk. Excellent tobacco is grown in Shemsdinan for export to Persia.

(3) LAKE VAN, called Arsissa Palus and also Thospitis from its Armenian names, is roughly rectangular 55 m. long and 40 broad, with a long north-eastern arm which increases the greatest length to 80 m. It stands about 5260 ft. above sea-level. It is without an outlet, and its greatest depth is along the southern shore. It has constant steady fluctuations, rising and falling some 8 ft. in a periodic movement of five years. In the middle of the 19th century a sudden rise submerged several places on the banks, including Arjish Kale, and the waters did not again subside. The north-eastern arm is much shallower than the rest. The water is bitter and undrinkable, being largely impregnated with carbonate and sulphate of soda with some borax. The salts are evaporated in pans, and called *perek*, being sold for washing purposes. There is, however, good water along the coast from springs and streams.

The lake has been navigated from the earliest times, and about 80 sailing boats, carrying about 20 tons burden, now ply on it, chiefly with wheat and firewood. Severe storms make navigation dangerous in winter. The southern shore is fringed by a steep range of mountains, with several thriving villages along the coast. The hills have now been almost denuded of trees. At the south-eastern corner is the island of Akhtamar with its ancient church, erected (*c.* 928) by Gagig, first king of the Ardzrunian dynasty. The Catholicos of Akhtamar is one of the highest offices in the Armenian Church, and dates from 1113. The small islands of Lim and Gdutz have also monasteries and churches. Large numbers of *darekh*, a kind of herring, exist in the lake, and are caught in nets from boats or when they enter the shallow lagoons in the spring and summer. Either fresh or salted they form an important article of diet of the poorer people.

See Sayce, "Cuneiform Inscriptions of Lake Van," in *Journal of Royal Asiatic Society*, vols. xiv., xx. and xxvi.; Lynch, *Armenia*, vol. ii. (1901); Belck and Lehmann, papers in *Verhand. d. Berliner Ges. für Anthropologie* (1892–99); *Zeit. für Ethnologie* (1892, 1899); *Mitt. d. Geog. Ges.* (Hamburg, 1898, 1899). (C. W. W.; F. R. M.)

VAN, an homonymous word, whose different meanings have no etymological connexion. In the most common sense "van" is merely an abbreviation of the Oriental word "caravan" (*q.v.*), and is applied to any large covered cart or vehicle used for the conveyance of goods, especially furniture, or, on railways, to a closed carriage for passengers' luggage, or for the accommodation of the guard. In the sense of the front portion of an army or fleet, or the advanced portion of any body, actually or metaphorically, "van" represents the French *avant* (Lat. *ab ante*), in front, as in *avant-garde*, van-guard, the earliest form in which the word came into English. Lastly, the word is used as a variant of "fan" (Lat. *vannus*), for a contrivance for winnowing grain, for a bird's wing, and in mining to an appliance for separating ore by washing.

VANADINITE, a mineral consisting of lead chloro-vanadate, $(PbCl)Pb_4(VO_4)_3$, crystallizing in the hexagonal system and isomorphous with pyromorphite and mimetite (*q.v.*). The crystals are usually six-sided prisms terminated by the basal planes, but are sometimes modified by numerous pyramidal planes which exhibit parallel hemihedrism. Rounded crystals and groups also occur. The colour is usually light brown or yellow, but crystals from Arizona are bright red. Owing to isomorphous replacement of the vanadium by phosphorus and arsenic, the specific gravity varies from 6·6 to 7·2; a variety containing much arsenic is called *endlichite*. The hardness is 3. The mineral is one of secondary formation in veins of lead ore. It was first found in Mexico, and in 1801 was asserted to contain a new element, which was called "erythronium"; this was later proved to be identical with the subsequently discovered element vanadium. Other well-known localities are Wanlockhead in Dumfriesshire, Kappel (Eisen-Kappel), near Klagenfurt in Carinthia, Arizona and New Mexico. (L. J. S.)

VANADIUM [symbol, V; atomic weight, 51·2 (O=16)], a metallic chemical element. It was first mentioned in 1801 by M. del Rio (*Gilb. Ann.*, 1801, 71, p. 7), but subsequently thought by him to be an impure chromium. Later, it was examined by N. G. Sefström, who found it in the slags of the Taberg iron ores (*Pogg. Ann.*, 1830, 21, p. 48), by J. J. Berzelius (ibid., 1831, 22, p. 1), and finally by Sir H. Roscoe (*Trans. Roy. Soc.*, 1868–1870), who showed that the supposed vanadium obtained by previous investigators was chiefly the nitride or an oxide of the element. In his researches, Roscoe showed that the atomic weight of the metal as determined by Berzelius and the formulae given to the oxides were incorrect, and pointed out that the element falls into its natural place in group V of the periodic classification along with phosphorus and arsenic, and not in the chromium group where it had originally been placed.

In small quantities, vanadium is found widely distributed, the chief sources being vanadite, mottramite, descloizite, roscoelite, dechenite and pucherite, whilst it is also found as a constituent of various clays, iron-ores and pitchblendes. Vanadium salts may be obtained from mottramite by digesting the mineral with concentrated hydrochloric acid, the liquid being run off and the residue well washed; the acid liquid and the washings are then evaporated with ammonium chloride, when ammonium metavanadate separates. This is recrystallized and roasted to vanadium pentoxide, which is then suspended in water into which ammonia is passed, when ammonium metavanadate is again formed and may be purified by recrystallization. The pure metal may be obtained by reducing vanadium dichloride in hydrogen, the operation being exceedingly difficult (for details, see Roscoe's original papers). In a somewhat impure condition it may be obtained by the reduction of vanadium pentoxide with a mixture of the rare earth metals which are obtained by reduction of the waste oxides formed in the manufacture of thoria (Weiss and Aichel, *Ann.*, 1904, 337, p. 380); from the oxide by Goldschmidt's thermite method (Koppel and Kaufmann, *Zeit. anorg. Chem.*, 1905, 45, p. 352); by electrolysis in a bath of fused fluorspar containing a steel cathode and an anode composed of carbon and vanadium pentoxide (M. Gin, *L'Électricien*, 1903, 25, p. 5); and by the electrolysis of vanadium trioxide when heated in an evacuated glass tube (W. v. Bolton, *Zeit. f. Elektrochem.*, 1905, 11, p. 45). H. Moissan (*Comptes rendus*, 1896, 122, p. 1297) obtained a vanadium containing from 10 to 16% of carbon by fusing vanadic anhydride with carbon in the electric furnace. For other methods of obtaining vanadium and its compounds, see Cowper Cowles, *Engin. and Mining Journ.* 67, p. 744; Herrenschmidt, *Comptes rendus*, 1904, 139, p. 635; M. Gin, *Elektrochem. Zeit.*, 1906, 13, p. 119; W. Prandtl and B. Bleyer, *Zeit. anorg. Chem.*, 1909, 64, p. 217.

Vanadium is a light-coloured metal of specific gravity 5·5. It is not volatilized even when heated to redness in a current of hydrogen, and it burns readily to the pentoxide when heated in oxygen. It dissolves slowly in hydrofluoric acid and in nitric acid, the solution turning blue; it is insoluble in hydrochloric acid. When fused with caustic soda, hydrogen is liberated and a vanadate is formed. It precipitates platinum, gold and silver from solutions of their salts, and also reduces mercuric, cupric and ferric salts. It absorbs nitrogen when heated in a current of that gas, forming a nitride. Vanadium may be detected by converting it into the pentoxide, which on passing sulphuretted hydrogen through its acid solution becomes reduced to the dioxide, the solution at the same time becoming lavender blue in colour; or if zinc be used as a reducing agent, the solution becomes at first green and ultimately blue.

Five oxides of vanadium are known (cf. NITROGEN), the mono-, di- and trioxides being basic in character, the tetra- and pentoxides being acidic and also feebly basic. The *monoxide*, V_2O, is formed when the metal is oxidized slowly in air. In a hydrated form it is obtained by the reduction of vanadyl monochloride, VOCl, with sodium amalgam, being precipitated from the liquid by the addition of ammonia (Locke and Edwards, *Zeit. anorg. Chem.*, 1899, 19, p. 378). The *dioxide*, V_2O_2, is formed in the reduction of vanadyl trichloride by hydrogen (Roscoe). It is a grey powder which is insoluble in water, but dissolves in acids to give a lavender-blue solution which possesses strong reducing properties. The addition of ammonia to this solution precipitates a brown hydrated oxide. The dioxide when heated in oxygen burns, forming the pentoxide. The *trioxide*, V_2O_3, is formed when the pentoxide is reduced at a red heat in a current of hydrogen, or by the action of oxalic acid on ammonium metavanadate. It forms a black amorphous powder or a dark green crystalline mass, and is insoluble in water and in most acids. The *tetroxide*, V_2O_4, results when the pentoxide is heated with dry oxalic acid and the resulting mixture of the tri- and pentoxide is warmed in the absence of air, or when the pentoxide is reduced by sulphur dioxide. It is an amorphous or crystalline mass of indigo-blue or steel-grey colour, which is insoluble in water and is also infusible. It oxidizes slowly in moist air, and dissolves easily in acids with the formation of blue solutions. The *pentoxide*, V_2O_5, is obtained when ammonium metavanadate is strongly heated, on calcining the sulphide, or by the decomposition of vanadyl trichloride with water. According to Ditte (*Comptes rendus*, 101, p. 698) it exists in three forms: a red amorphous soluble form which results when ammonium metavanadate is heated in a closed vessel and the residue oxidized with nitric acid and again heated; a yellow amorphous insoluble form which is obtained when the vanadate is heated in a current of air at 440° C.; and a red crystalline form which is almost insoluble in water. It is soluble in hot concentrated sulphuric acid and in concentrated hydrochloric acid. It is an energetic oxidizing agent and is consequently readily reduced when heated with various metals (zinc, magnesium, &c.), with carbon and with oxalic acid. On fusion with the caustic alkalis and alkaline carbonates it yields vanadates. It forms numerous compounds with potassium fluoride. Many complex derivatives are known, such, for example, as phosphor-vanadates, arsenio-vanadates, tungsto-vanadates, molybdo-vanadates, &c. For the use of this oxide in the electrolytic oxidation and reduction of organic compounds, see German Patents 172654 (1903) and 183022 (1905).

Many salts of oxy-acids of vanadium are known, but of the more common oxy-acids, metavanadic acid, HVO_3, and pyrovanadic acid, $H_4V_2O_7$, alone appear to have been isolated. *Metavanadic acid* is obtained in the form of yellow scales by boiling copper vanadate with an aqueous solution of sulphur dioxide. It is only very slightly soluble in water. *Pyrovanadic acid* is deposited as a dark brown unstable powder when an acid vanadate is decomposed by nitric acid. Of the salts of these acids, those of the ortho- and pyro-acids are the least stable, the orthovanadates being obtained on fusion of vanadium pentoxide with an alkaline carbonate. The metavanadates are usually yellowish or colourless solids. Ammonium metavanadate is obtained when the hydrated vanadium pentoxide is dissolved in excess of ammonia and the solution concentrated. It has been used in dyeing with aniline black. Tetra- and hexavanadates have also been described (see Ditte, *Comptes rendus*, 104, pp. 902, 1061; 102, p. 918; Manasse, *Ann.* 240, p. 23). The hypovanadates are insoluble in water, except those of the alkali metals, which are obtained by the addition of caustic alkalis to concentrated solutions of the chloride or sulphate of the tetroxide. They are brown in colour and easily oxidize. Pure hypovanadic acid has been obtained by G. Gain (*Comptes rendus*, 1906, 143, p. 823) by calcining ammonium metavanadate and saturating a solution of the resulting oxides with sulphur dioxide; the resulting blue solution (from which a sulphate of composition $2V_2O_4 \cdot 3SO_2 \cdot 10H_2O$ can be isolated) is then boiled with water, when sulphur dioxide is liberated and a pale red crystalline powder of hypovanadic acid, $H_4V_2O_5$, is precipitated.

Vanadium dichloride, VCl_2, is a green crystalline solid obtained when the tetrachloride is reduced with hydrogen at a dull red heat. It is very deliquescent and readily soluble in water. The *trichloride*, VCl_3, is a deliquescent solid formed when the tetrachloride is heated in a retort as long as chlorine is given off (Roscoe), or by heating vanadium trisulphide in a current of chlorine and fractionally distilling the resulting product at 150° C. in a current of carbon dioxide (Halberstadt, *Ber.*, 1882, 15, p. 1619). The *tetrachloride*, VCl_4, is formed by the direct union of vanadium and chlorine or by the action of sulphur chloride on vanadium pentoxide (Matignon, *Comptes rendus*, 1904, 138, p. 631). It is a fuming liquid, which is soluble in benzene and in acetic acid; it dissolves in water to form a deep blue solution. Several oxychlorides have also been described. *Vanadium carbide*, VC, was prepared by H. Moissan (*Comptes rendus*, 1896, 122, p. 1297) by heating vanadium pentoxide and carbon for a few minutes in the electric furnace. It is a volatile compound which burns when heated in oxygen and which is unacted upon by sulphuric and hydrochloric acids.

For vanadium steels, see IRON AND STEEL MANUFACTURE.

VAN BEERS, JAN (1821–1888), Belgian poet, usually called "the elder" to distinguish him from his son, Jan van Beers, the well-known painter, was born at Antwerp on the 22nd of February 1821. He was essentially a Netherlander, though politically a Belgian, expressing his thoughts in the same language as any North Netherland writer. In fact, the poems of Jan van Beers are perhaps more popular in Holland than in Belgium, and of many of them there exist more editions printed in Holland than in his political fatherland. Van Beers started life as a teacher of Dutch language and literature, first at Malines, then at Lierre, and in 1860 was appointed a professor of both at the Athenaeum (high school) in Antwerp, where he had also been a sub-librarian in the communal library. Van Beers as a teacher was early in the field, with Hendrik Conscience, Willems and others, when the Flemish movement began. He composed a Dutch grammar (1852), which, in enlarged editions, still holds the field, and a volume of selections from Dutch authors, both books being so much appreciated that the Belgian government made them text-books in the public schools. Van Beers's historical poems, the principal of which is, perhaps, *Jakob Van Maerlant* (Amsterdam, 1860), helped the Flemish revival in Belgium as powerfully as his school-books. He is best known, however, as the writer of ballads and songs. *Jongelingsdroomen* ("A Young Man's Dreams") first appeared at Antwerp and Amsterdam in 1853. These poems were followed by *Levensbeelden* ("Life Figures or Pictures," Amsterdam, 1858) and by *Gevoel en Leven* ("Feeling—Living," Amsterdam, 1861). His *Rijzende Bladen* ("Rising Leaves") first made its appearance at Ghent and Rotterdam in 1883. In the following year an *édition de luxe* of his poetry was published, adorned with pen-and-ink sketches by Jan van Beers the younger, and a popular edition of his collected poems was published at Ghent and Rotterdam in 1873 and 1884. Among the best known are *De Blinde* ("Blind"), *De Zieke Jongeling* ("Young and Doomed"), *Bij 't Kerkportaal* ("At the Church Porch"). Van Beers's poetry, full of glow and pathos, simple yet forcible, is somewhat akin to that of Longfellow. Van Beers died at Antwerp on the 14th of November 1888.

VANBRUGH, SIR JOHN (1664–1726), British dramatist and architect, was born in the parish of St Nicolas Acons in the City of London, and christened on the 24th of January 1664. His grandfather, Gillis van Brugg, of Ghent, migrated to England in the reign of James I., was naturalized, resided as a merchant and was buried in the parish of St Stephen's Walbrook. The dramatist's father, Giles (1631–1689), a wealthy sugar baker, who married into the Carleton family, was driven from London by the plague and settled at Chester. The mother (Elizabeth Carleton, of the Dorchester family) survived to see her son famous; she died at Claygate, near Esher, in 1711, and was buried at Thames Ditton. After a few years at the King's School, Chester, John at nineteen was sent to France to study the arts; after two years' absence he returned to take up a commission in the regiment soon to be known as the 13th Foot. In the early autumn of 1690 Vanbrugh was arrested at Calais on a charge of espionage. The informant against him was a lady. He was imprisoned at Vincennes, but on the 1st of Feb. 1692, by a *lettre de cachet*, he was removed to the Bastille. On the 12th of November he found surety to the extent of one thousand pistoles, but was confined to the fortifications of Paris until his exchange was effected on the cartel. His enforced leisure was responsible for the first draft of the *Provok'd Wife*. Voltaire said in his *Lettres sur les Anglais* that he could not imagine what had gained such a comic writer the distinction of detention in such a grim fortress. As a matter of fact, a considerable number of English officers were arrested about this time on a similar charge, as may be seen from the Bastille archives.[1] For a time after his return he resumed his commission and was known as Captain Vanbrugh.

The production of Cibber's *Love's Last Shift* at the Theatre Royal in January 1696 kindled afresh his attachment to the comic muse. He thought it would be interesting to develop the situation upon which Cibber had rung down the curtain, and the result was *The Relapse*, "got, conceived and born in six weeks' space." It was given on Boxing Day 1696, with Cibber as Foppington, one of the three parts borrowed from the preceding comedy. The Sir Novelty Fashion of Cibber was developed in this play into Lord Foppington, who has been pronounced "the best fop ever brought upon the stage." The play has been revived in various forms: Sheridan adapted it in *A Trip to Scarborough*, and it inspired two modern versions in 1870 and 1890, *The Man of Quality* and *Miss Tomboy*. *Aesop*—produced at Drury Lane immediately after *The Relapse*—was an adaptation of Boursault's dramatic sermon on the same subject. It ran for a week only, but the success of *The Relapse* was so triumphant that Montague, afterwards Lord Halifax, asked at once for the *Provok'd Wife* for the theatre in Lincoln's Inn Fields, and it was produced at that theatre in May 1697. All that could be said in answer to those who condemned it on account of its unblushing libertinism was that Sir John Brute is sufficiently brutal to drive any woman into rebellion, and that since the glorious days of the Restoration a wife's rebellion and a wife's adultery were synonymous terms. The play was a complete triumph, and Brute was one of Garrick's great parts. Vanbrugh was fiercely attacked by Jeremy Collier for immorality in 1698, and wrote nothing more for the stage until 1700, when an adaptation of the *Pilgrim* of Beaumont and Fletcher was produced at Drury Lane. In this play, in the part of Alinda, Anne Oldfield scored her first success. Two years later appeared *The False Friend*, a version of Le Sage's *Traître puni*. Other adaptations from the French were *A Country House*, from Dancourt's *Maison de campagne*; *Confederacy* (1705), from the same author's *Bourgeoises à la mode*; *Squire Treloohy* (1704), a version of Molière's *Monsieur de Pourceaugnac*; and *The Mistake* (1705), from Molière's *Dépit amoureux*.

Collier's attack and the resulting movement must have been responsible in part for "Van" turning his attention to architecture. The demand for splendid country seats in the new Palladian style was steadily increasing, and his reputation as a modern wit was an introduction in itself. In 1702 he was entered as comptroller of the Royal Works (now the Board of Works, where several of his designs may still be seen). In 1703 he wrote to ask his friend Jacob Tonson to procure him a "Palladio," and in the same year he was a commissioner at Greenwich, where the secretary William Vanbrugh was a kinsman of his own, whom Evelyn had appointed at his request. In the meantime, Vanbrugh had been appointed architect to the earl of Carlisle, and the result, completed in 1714, was the Corinthian mansion of Castle Howard. The work is an extension of the Palladian plan introduced by Inigo Jones, with the addition of immense corridors in segmental colonnades leading from the main entrance to the wing blocks. From a scenic artist's point of view, it is a magnificent (and certainly his best) piece of work. The earl, then deputy earl-marshal, testified his satisfaction by procuring for Vanbrugh a high place in the College of Arms. In March 1704 he was actually promoted Clarenceux, though he not only knew nothing of heraldry but had openly ridiculed that grave science in *Aesop*. The indignant college protested in vain, and the architect stuck to his place. His next work was to prepare designs for Kneller Hall near Hounslow. But the success of Castle Howard now caused him to entertain the rash project of building a theatre in the Haymarket, from his own design, for the acting of his own plays. The joyous courage with which, having persuaded thirty people in the fashionable world to aid him in finding the money, and Congreve to aid him in finding the plays, he began to build in perfect unconsciousness of the danger before him, is the only passage in his life which may be called pathetic, save of course his struggle with the "wicked woman of Marlborough." The magnitude of Vanbrugh's architectural ideas grew as the work went on, and with the ideas the structure grew till a theatre meant for the delicate *bijouterie* work of polite comedy seemed growing to the proportions of the Roman Colosseum. Whether Congreve endeavoured to put a check upon his friend's architectural and authorial fervour does not appear. But it must be remembered that not only Vanbrugh's plays but his own were to be acted there, and that, although Congreve was a man of great sagacity, no man, not even he who pretended to set his gentility above his genius, is sagacious when confronted by the surpassing excellence of his own poems and plays. When at length the time came to test the acoustics of the pile, it was found to be sadly defective. What changes were made to rectify the errors of structure docs not appear. The theatre was opened to the public with an Italian opera, which was followed by three of Molière's comedies, and these by the *Confederacy*, Vanbrugh's masterpiece on the whole, though perhaps its finest scenes are not equal to the finest scenes in *The Relapse*.

Vanbrugh at last withdrew from the disastrous speculation; Congreve had already withdrawn. But a man to whom Fortune had been so kind as she had been to Vanbrugh could hardly be depressed by any of her passing frowns. Queen Anne at once sent him abroad on an important state errand, and afterwards

[1] Ravaisson; and Funck-Brentano, *Liste des prisonniers de la Bastille.*

he was commissioned to build Blenheim. Upon the merits and demerits of this famous "hollowed quarry" there has been much conflict of opinion. As to the sarcasms by Swift, Walpole, Evans, and the rest, they are as nothing when set against Sir Joshua Reynolds's defence of Vanbrugh and his style. Blenheim Palace is probably the largest domestic building in England, and consists of three blocks, the centre containing the private living rooms, one wing the stables, and the other the kitchens and storehouses. It is planned on a colossal scale. Vanbrugh considered a building and the parts of a building as simply so much material for effect, without regard to their reasonable use and the necessary limitations of design. Thus he would support his main block by subordinate groups without considering for a moment the inconvenience that might be caused by the kitchen being removed by four hundred yards from the dining-room. Personal comfort was sacrificed to perspective. Windows were to adorn the elevation, not to light the interior; and, as Voltaire said, if the rooms had only been as wide as the walls were thick, the château would have been convenient enough. After Blenheim and Castle Howard, his next largest palace was probably Fleurs, near Kelso. His plans were only suitable to the largest kind of palace. Blenheim, however, was a source of great sorrow to the kindly dramatist. Though parliament had voted for the building of it, no provision had been made for the supplies. The queen while she lived paid them, and then Vanbrugh was left to the meanness of the duke of Marlborough, and afterwards to the insolence of the "wicked woman," who did her best to embitter his life. Besides Castle Howard and Blenheim, he built many other country mansions, such as Grimsthorpe and Duncombe Hall in Yorkshire, Eastbury in Dorsetshire, Seaton-Delaval in Northumberland, King's Weston near Bristol, Oulton Hall in Cheshire, old Claremont House at Esher, old Eaton Hall, Iver Grove, Bucks. He also restored Kimbolton Castle for the earl of Manchester. In 1716 he became architect to Greenwich Hospital.

In January 1719 Vanbrugh married Henrietta Maria, daughter of Colonel Yarborough of Heslington, and four years afterwards, at the accession of George I., he was knighted. He afterwards wrote again for the stage, and the unfinished fragment of the *Journey to London* (completed by Cibber as *The Provok'd Husband* in 1728) shows that his powers remained to the last as fine as ever. His married life was mostly spent at Blackheath, very probably in "Bastile House" on Maze Hill, repaired in 1904 and now known as Vanbrugh Castle. His wife died there at a great age in 1776, but "Van" himself died on the 26th of March 1726 in his modest town house, built in 1703 out of the ruins of Whitehall and satirized by Swift as the "goose pie." The site is occupied to-day by the War Office. The famous epitaph, "Lie heavy on him, earth," is attributed to Abel Evans. The best portrait of the dramatist is the kit-cat by Kneller.

Vanbrugh's works were edited in 2 vols., 1893, by W. C. Ward (portraits). *Select Plays* were issued in the Mermaid Series (ed. A. E. H. Swaen) in 1896. See G. H. Lovegrove's *Life, Works and Influence of Sir John Vanbrugh* (1902), Max Dametz's *Vanbrughs Leben und Werke* (1898), and *Swift's Works* (Bohn), xii. 80 sq. (T. Se.)

VAN BUREN, MARTIN (1782–1862), eighth president of the United States, was born at Kinderhook, New York, on the 5th of December 1782, of Dutch descent. His father was a farmer and tavern-keeper. His education was limited to that which could be obtained in the common schools and at Kinderhook Academy, and there is testimony to the effect that as late as 1829, when he became secretary of state, he wrote crudely and incorrectly. In 1796 he began the study of law, completing his preparation in 1802 at New York, where he studied under William Peter Van Ness (1778–1826), an eminent lawyer and later Aaron Burr's second in the duel with Alexander Hamilton. Van Buren made the acquaintance of Burr, but did not fall under his influence. In 1803 he was admitted to the bar and continued in active and successful practice for twenty-five years. His practice made him financially independent, and paved the way for his entrance into politics. New York politics after 1800, the year of the election of Jefferson and the downfall of the Federalists, were peculiarly bitter and personal. The Republicans were divided into three factions, followers respectively of George Clinton (and later of his nephew, De Witt Clinton), Robert R. Livingston and Aaron Burr; and such Federalist control as there was from time to time after 1799 depended upon coalition with one or other of these groups. Van Buren, who early allied himself with the Clintonians, was surrogate of Columbia county from 1808 until 1813, when he was removed. In 1812 he entered the state Senate, and he also became a member of the court for the correction of errors, the highest court in New York until 1847.

His career in the Senate covered two terms (1812–1820). In 1815 he became attorney-general, an office which he held, still as a member of the Senate, until 1819, when he was displaced to make room for a Federalist. He had already, in 1808, removed from Kinderhook to Hudson, and in 1816 he took up his residence in Albany, where he continued to reside until he entered Jackson's cabinet in 1829. As a member of the state Senate he supported the War of 1812 and drew up a classification act for the enrolment of volunteers. He was chosen to draft the resolution of thanks voted by the legislature to General Andrew Jackson after the battle of New Orleans. He broke with De Witt Clinton in 1813, but nevertheless favoured, in 1817, Clinton's plan for the Erie Canal. His attitude towards slavery at the moment was shown by his vote, in January 1820, for a resolution opposing the admission of Missouri as a slave state. In the same year he was chosen a presidential elector. It is at this point that Van Buren's connexion began with so-called "machine politics," a connexion which has made his name odious to some historians of the period. He was a leading member of the "Albany regency," a group of politicians who for more than a generation controlled the politics of New York and powerfully influenced those of the nation, and which did more than any other agency to make the "spoils system" a recognized procedure in national, state and local affairs. Van Buren did not originate the system, for it was already well developed when he entered public life; but the nickname of "Little Magician" which presently attached to him testifies to the skill with which he exploited it, and to the popular impression which his political methods produced.

In February 1821 he was elected to the United States Senate. Before taking his seat he served also as a member of the state constitutional convention, where he opposed the grant of universal suffrage. His course in the Senate was not altogether consistent, though in this respect he is not to be judged more harshly than some of his associates. He at first favoured internal improvements, and in 1824 proposed a constitutional amendment to authorize such undertakings, but the next year took ground against them. He voted for the tariff of 1824, then gradually abandoned the protectionist position. In the presidential election of 1824 he appeared as a strong supporter of William H. Crawford, and received the electoral vote of Georgia for vice-president; but he shrewdly kept out of the acrimonious controversy which followed the choice of John Quincy Adams. He early recognized the availability of Andrew Jackson, however, as a presidential candidate, and after the election sought to bring the Crawford and Jackson followers together, at the same time strengthening his control as a party leader in the Senate. Always notably courteous in his treatment of opponents, he showed no bitterness either towards J. Q. Adams or Henry Clay, and voted for Clay's confirmation as secretary of state notwithstanding the "corrupt bargain" charge; at the same time he opposed internal improvements and declined to support the proposal for a Panama Congress. As chairman of the judiciary committee, he brought forward a number of measures for the improvement of judicial procedure, and in May 1826 joined with Benton in presenting a report on executive patronage. In the debate on the "tariff of abominations" in 1828 he took no part, but voted for the measure in obedience to instructions from the New York legislature—an action which was cited against him as late as the presidential campaign of 1844. Van Buren was not an orator, but his more important speeches show careful preparation and his opinions carried weight; and the oft-repeated charge that he refrained from declaring himself on crucial questions is hardly borne out by an examination of his senatorial career. In February 1827 he was re-elected to the Senate by a large majority. He was now one of the recognized managers of the Jackson campaign, and a tour of Virginia, the Carolinas and Georgia in the spring of 1827 won support for Jackson from Crawford.

In 1828 Van Buren was elected governor of New York for the term beginning on the 1st of January 1829, and resigned his seat in the Senate. But on the 5th of March he was appointed by President Jackson secretary of state, an office which probably had been assured to him before the election, and he resigned the governorship. As secretary of state he took care to keep on good terms with the "kitchen cabinet," the group of politicians who acted as Jackson's advisers, and won the lasting regard of Jackson by his courtesies to Mrs John H. Eaton, wife of the secretary of war, with whom the wives of the cabinet officers had refused to associate. He did not oppose Jackson in the matter of removals from office, but was not himself an active "spoilsman," and protested strongly against the appointment of Samuel Swartwout (1783–1856), who was later a defaulter to a large amount as collector of the port of New York. He skilfully avoided entanglement in the Jackson-Calhoun imbroglio. No diplomatic questions of the first magnitude arose during his service as secretary of state, but the settlement of long-standing claims against France was prepared for, and trade with the British West India colonies was opened. In the controversy with the Bank of the United States he sided with Jackson. After the breach between Jackson and Calhoun, Van Buren was clearly the most prominent candidate for the vice-presidency. Jackson in December 1829 had already made known his own wish that Van Buren should receive the nomination. In April 1831 Van Buren resigned, though he did not leave office until June. In August he was appointed minister to England, and arrived in London in September. He was cordially received, but in February learned that his nomination had been rejected by the Senate on the 25th of January. The rejection, ostensibly attributed in large part to Van Buren's instructions to Louis McLane, the American minister to England, regarding the opening of the West India trade, in which reference had been made to the results of the election of 1828, was in fact the work of Calhoun, the vice-president; and when the vote was taken enough of the majority refrained from voting to produce a tie and give Calhoun his longed-for "vengeance." No greater impetus than this could have been given to Van Buren's candidacy for the vice-presidency. After a brief tour on the Continent he reached New York on the 5th of July. In May the Democratic convention, the first held by that party, had nominated him for vice-president on the Jackson ticket, notwithstanding the strong opposition to him which existed in many states. No platform was adopted, the widespread popularity of Jackson being relied upon to win success at the polls. His declarations during the campaign were vague regarding the tariff and unfavourable to the United States Bank and to nullification, but he had already somewhat placated the South by denying the right of Congress to abolish slavery in the District of Columbia without the consent of the slave states. In the election he received 189 electoral votes, while Jackson received 219 for President. Jackson now determined to make Van Buren president in 1836, and bent all his energies to that end. In May 1835 Van Buren was unanimously nominated by the Democratic convention at Baltimore. He expressed himself plainly during the canvass on the questions of slavery and the bank, at the same time voting, perhaps with a touch of bravado, for a bill offered in 1836 to subject abolition literature in the mails to the laws of the several states. Calhoun, bitterly hostile to the last, objected to the usual vote of thanks to the retiring vice-president, but withdrew his objection. In the election Van Buren received 170 electoral votes against 73 for William Henry Harrison, his principal opponent; but the popular vote showed a plurality of less than 25,000 in a total vote of about 1,500,000. The election was in fact a victory for Jackson rather than for Van Buren.

The details of Van Buren's administration belong to the history of the United States (see UNITED STATES). He announced his intention "to follow in the footsteps of his illustrious predecessor," took over all but one of Jackson's cabinet, and met with statesmanlike firmness the commercial crisis of 1837, already prepared for before he took office. No exhibition of ability or courage, however, nor yet the most skilful manipulation of the political machinery of the party, could prevent continued hostility to him and to the methods for which he was widely believed to stand. The state elections of 1837 and 1838 were disastrous for the Democrats, and the partial recovery in 1839 was offset by a second commercial crisis in that year. Nevertheless, Van Buren was unanimously renominated by the Democrats in 1840. Charged with being "a Northern man with Southern principles," he was frequently interrogated during the campaign, and his nomination obviously failed to arouse enthusiasm or even inspire confidence. The revolt against Democratic rule was undoubtedly serious, but a study of the popular vote shows that the election of Harrison, the Whig candidate, was less of a revolution than many affected to think. On the expiration of his term Van Buren retired to his estate at Kinderhook, but he did not withdraw from politics or cease to be a figure of national importance. It was even proposed to make him a member of the Federal Supreme Court in order to get him out of political life. He confidently expected to be nominated for president in 1844, and his famous letter of the 27th of April, in which he frankly opposed the immediate annexation of Texas, though doubtless contributing greatly to his defeat, was not made public until he felt practically sure of the nomination. In the Democratic convention, though he had a majority of the votes, he did not have the two-thirds which the rule of the convention required, and after eight ballots his name was withdrawn. In 1848 he was again nominated, first by the "Barnburner" faction of the Democrats, then by the Free Soilers, with whom the "Barnburners" coalesced, but no electoral vote was won by the party. In the election of 1860 he voted for the fusion ticket in New York which was opposed to Abraham Lincoln, but he could not approve of President Buchanan's course in dealing with secession, and later supported Lincoln. He died in Kinderhook on the 24th of July 1862. His memoirs, to 1834, remain unpublished, but an *Inquiry into the Origin and Course of Political Parties in the United States* was compiled from it by his sons and published in 1867. Van Buren married in 1807 Hannah Hoes (1782–1819), by whom he had four sons.

Van Buren's son ABRAHAM (1807–1873) graduated at West Point in 1827, served under General Winfield Scott against the Seminole Indians in 1836, and was made captain of the First Dragoons. In 1837 he resigned from the army to become his father's private secretary, but in 1846, at the outbreak of the war with Mexico, he was reappointed with the rank of major and paymaster. In August 1847 he was breveted lieutenant-colonel for gallant and meritorious conduct at Contreras and Churubusco. In 1854 he retired to private life. Another son, JOHN (1810–1866), graduated at Yale in 1828, was admitted to the bar at Albany in 1830 and was attorney-general of New York in 1845–1846. He was popularly known as "Prince John" because of his manners and appearance.

The best biography of Van Buren is by Edward M. Shepard, in the "American Statesmen Series" (revised ed., Boston, 1899). The Life by George Bancroft (New York, 1889) is highly eulogistic. Von Holst's *United States*, MacDonald's *Jacksonian Democracy*, Garrison's *Westward Extension* and T. C. Smith's *Parties and Slavery* (the last three in the "American Nation Series") give much attention to Van Buren's public career. The Van Buren manuscripts are in the Library of Congress. (W. MacD.*)

VANCE, ZEBULON BAIRD (1830–1894), American political leader, was born in Buncombe county, North Carolina, on the 13th of May 1830. He was educated at Washington College, at Salem, Tennessee, and the university of North Carolina (1851–52). Entering politics as a Whig, he was elected solicitor of Buncombe county (1852) and a member of the state House of Commons (1854), and served in the national House of Representatives from December 1858 until the 3rd of March 1861. As captain of a company in the 14th and as colonel of the 26th North Carolina regiments, he took part in the Virginia campaigns of 1861–62. From 1862 until the close of the war he was governor of the state, and from the 20th of May to the 5th of July 1865, when he was released on parole, was held as a prisoner by the United States authorities in Washington. Having been elected to the United States Senate in 1870 and been refused admission because his disabilities—due to his participation in the war—had not been removed, he took the lead in the fight against "carpet-bag" misrule and was chosen governor in the political revolution of 1876, serving in 1877–79. He was again elected to the Senate in 1878 and was re-elected in 1884 and 1890, serving from March 1879 until his death. Senator Vance was a typical Southern Whig. He disliked slavery and he hated secession. In common with other Whigs, he was forced to remain in the Democratic party after the war by the fear of negro domination. He died at Asheville, North Carolina, on the 14th of April 1894.

See the Life by Clement Dowd (Charlotte, N.C., 1897).

VANCOUVER, GEORGE (*c.* 1758–1798), English navigator, was born in 1758. He entered the navy at the age of thirteen, and accompanied James Cook in his second (1772–74) and third (1776–80) voyages of discovery. After serving for several years in the West Indies, both under Rodney (his commander in the action of the 12th of April 1782) and under Alan Gardner (1786–89), Vancouver, on Gardner's recommendation, was appointed to command an expedition to the north-west coast of America, to take over from the Spaniards the territory they had seized (and subsequently relinquished) in that region, to explore the coast from 30° N. round to Cook's River (or Inlet), to search for an eastward passage to the great lakes, and to ascertain the true character of Juan de Fuca Strait. Vancouver, accompanied by Lieutenant Broughton, left Falmouth on the 1st of April 1791 and proceeded by way of the Cape of Good Hope to Australia, where he carefully surveyed part of the south-west coast, especially King George's Sound, whose value as a harbour he pointed out. He next made for Dusky Bay, New Zealand (which he was the first properly to explore), and thence sailing north-east, discovered Oparo Islet (27° 36′ S.; 144° 12′ W.), and on the 30th of December reached Tahiti, where he was again joined by Broughton, who meanwhile had discovered Chatham Island. After staying about three weeks at Tahiti and several weeks at the Hawaiian Islands, Vancouver on the 18th of April 1792 sighted the west coast of North America (California, then known as New Albion) in 39° 27′ N. He examined the coast up to 52° 18′ N. with minute care, surveying all inlets, discovering the Gulf of Georgia, and circumnavigating Vancouver Island (named after him). After another visit (February–March 1793) to the Hawaiian Islands, in whose races and affairs he took great interest, Vancouver resumed his exploration of the American coast in April, surveying north to 56° N., and south (past the Spanish Californian settlements) to 35° N. During a fresh stay at the Hawaiian Islands (January–March 1794) Vancouver accepted their submission to Great Britain, but his annexation seems never to have been officially ratified. Quitting the group again in March 1794, Vancouver sailed, by Chernigov Island and Kodiak Island, to Cook's Inlet, which was now proved to be no river. After a fresh survey of much of the coast north of San Francisco, Vancouver set out homewards via Cape Horn and St Helena in October 1794. On the way he made a careful examination of Cape St Lucas, the southern point of Lower California, the Galapagos Islands and some other points. He reached the mouth of the Shannon on the 13th of September 1795 (the Thames on the 20th of October), and immediately set about the preparation of his narrative; but he died at Petersham in Surrey on the 10th of May 1798, before he had completed his task. His brother John, assisted by Captain Puget, published the complete record in 1798.

See *A Voyage of Discovery to the North Pacific Ocean and round the World . . . in 1790–5 . . . under Captain George Vancouver*, 3 vols. (1798), with an atlas of maps and plates.

VANCOUVER, a city and the county-seat of Clarke county, Washington, U.S.A., on the Columbia river about 100 m. from its mouth, about 5 m. E. of its confluence with the Willamette, and 8 m. N. of Portland, Oregon. Pop. (1890) 3545; (1900) 3126 (547 foreign-born); (1910) 9300. It is served by the Northern Pacific, the Great Northern, the Oregon & Washington, and the Spokane, Portland & Seattle railways, and by steamship lines, being accessible to sea-going vessels; a ferry connects with the Portland Electric railway. The city is the seat of St James College (Roman Catholic; 1856) and of the state school for defective youth (1886). Vancouver Barracks, east of the city, is an important U.S. military post (established in 1849) and the headquarters of the Military Department of the Columbia (including Washington, Oregon, Idaho, except the part in Yellowstone Park, and Alaska); the military reservation includes some 640 acres. The post commands an excellent view of the Columbia, and of the mountain peaks, Mt Hood, Three Sisters, Jefferson and St Helens. The city has a public library and a public park, and there is a U.S. Land Office here. Vancouver lies in a region of extensive forests and of fruit-growing and farming lands; among its manufactures are lumber products, barrels, condensed milk, flour, beer and canned fruit. It was a post of the Hudson's Bay Company in 1828–1846, and was protected by a large stockade, to which settlers fled for protection when attacked by the Indians. It was made the county-seat in 1854, was incorporated as a village in 1858 and was chartered as a city in 1889.

VANCOUVER, a city and port in the province of British Columbia, Canada, on the southern side of Burrard Inlet. Pop. (1906) about 45,000. It is the western terminus of the Canadian Pacific railway. The harbour of Vancouver is one of the finest natural harbours in the world. The city is the largest in British Columbia, and is the chief Canadian shipping port for Japan, China, Australia and the islands at which the C.P.R. mail steamers call. There are regular lines of steamers running between Vancouver and Alaska and the points of connexion with the Yukon territory, as well as lines to Puget Sound and San Francisco in the United States. The port also has regular and frequent communication by steamer with Victoria, and is the headquarters of an extensive coasting trade. In 1886, soon after its establishment, a fire swept the whole town out of existence, but the inferior wooden buildings at first erected have been largely replaced by stone and brick structures, giving a handsome appearance to the principal streets. Vancouver has well-paved streets and is well supplied with water, electric lighting, electric cars and all the improvements of a modern city. Stanley Park, a large reserve of 900 acres, is one of the principal pleasure resorts. There is also fine sea-bathing at English Bay on the outskirts of the city. The "McGill University College of British Columbia" at Vancouver is one of the colleges of McGill University (Montreal). There are a sugar refinery and cooperage works, as well as large sawmills, shingle factories and many other industrial concerns. A large wholesale trade is carried on with all the settlements of the province. Vancouver is the centre of the important timber industry of British Columbia.

VANCOUVER ISLAND, the largest of an archipelago of innumerable islands which fringes the Pacific coast of Canada, being at the same time the largest island on the west coast of North America. It forms part of British Columbia. It extends from 48° 20′ to 51° N. and from 123° to 128° 30′ W., and is thus 285 m. long and from 40 to 80 m. wide, with an area of about 20,000 sq. m., being nearly the size of Nova Scotia, which occupies a corresponding position on the Atlantic coast. It is bounded on the south by the Strait of Juan de Fuca, and is separated from the mainland of the province by the Strait of Georgia and Queen Charlotte Sound. A partially submerged range of mountains, which has been termed the Vancouver Range, runs parallel to the coast of British Columbia; a portion of this range forms Vancouver Island, and it again rises above the level of the sea farther north, forming the Queen Charlotte Islands. The coast-line is generally precipitous. The west coast is much broken by bays and inlets—the transverse valleys of the sunken range—which penetrate far inland. Among these may be mentioned the Alberni Canal, which is 20 m. long with a fine harbour at its head, the width of the inlet varying from a half to one mile; Nootka Sound, 6 m. wide, and sending three arms inland which are from 40 to 160 fathoms deep, as well as Clayoquot, Esperanza, Kyuquot and Quatsino Sounds, which also penetrate deeply into the island. The general height of the mountain-range on Vancouver Island is from 2000 to 3000 ft.; some peaks are 6000 ft.; and Victoria Peak is 7484 ft. high. The island is composed largely of crystalline and metamorphic rocks, but contains some cretaceous areas which hold extensive beds of coal, especially on the east coast. These are mined at Nanaimo, Ladysmith and other points. The island is covered everywhere with an exceedingly dense forest, which makes its interior very difficult to traverse, so that there are still portions of the island which have not been thoroughly explored. These forests yield immense supplies of magnificent timber, which together with the coal-field and fisheries constitute the chief resources of the island. There are some level tracts on the south-east coast, as well as in the narrow, well-watered valleys of the interior, which afford excellent agricultural land on which cereals of all kinds, as well as all the fruits of the temperate zone, flourish, and which are also suitable for raising sheep and cattle. The climate of Vancouver Island, especially in the south, is wonderfully mild for the latitude—as mild as that of Great Britain, with dryer summers. The mean temperature of December at Victoria in the south of the island is about 41° Fahr., while that of July is about 60°. In the north and west the rainfall is greater than on the south and east coasts. (F. D. A.)

VANDALS (Lat. *Vandili* or *Vandilii*), a term used by early writers only as a collective designation for a group of Teutonic tribes including, according to Pliny, the Burgundians and the Goths. As a tribal name Vandali occurs first in connexion with the Marcomannic War. The people to whom the name is there applied seem to be identical with those formerly known as Lugii. Another tribe called Silingae by Ptolemy likewise appears among the Vandals at a later time. Both these tribes appear to have inhabited the upper part of the basin of the Oder, and the name of the Silingae is preserved in Silesia. The Vandals figure in the earliest legends both of the Goths and the Lombards, both of whom they are said to have encountered unsuccessfully. They first came into contact with the Romans during the Marcomannic War. In the time of Aurelian they invaded Pannonia, and during the reign of Probus we find them fighting in Dacia. In the time of Constantine I., according to Jordanes, they suffered a great defeat at the hands of Geberich, king of the Goths, their own king Visimar being killed, and the survivors were allowed by the Romans to settle in Pannonia. Here they seem to have remained in subjection to the Romans for about sixty years. In the year 406 they moved westward, according to some writers at the instigation of Stilicho, who is himself said to have been of Vandal origin, and crossing the Rhine at Mainz proceeded towards Gaul. A portion of the nation is, however, said to have remained behind, and Procopius tells a story that these remnants sent an embassy to Gaiseric, asking that their kinsfolk in Africa should renounce their claims to the lands which their forefathers had held in the old homes of the race. (F. G. M. B.)

In Gaul the Vandals fought a great battle with the Franks, in which they were defeated with the loss of 2000 men, and their king Godégisel was slain. In 409 his son Gunderic led them across the Pyrenees. They appear to have settled in Spain in two detachments. One, the Asdingian Vandals, occupied Galicia, the other, the Silingian, Andalusia. Twenty years of bloody and purposeless warfare with the armies of the empire and with their fellow-barbarians, the Goths and the Suevi, followed. The Silingian Vandals were well-nigh exterminated, but their Asdingian brethren (with whom were now associated the remains of a Turanian people, the Alani, who had been utterly defeated by the Goths) marched across Spain and took possession of Andalusia.

In 428 or 429 the whole nation set sail for Africa, upon an invitation received by their king from Bonifacius, count of Africa, who had fallen into disgrace with the court of Ravenna. Gunderic was now dead, and supreme power was in the hands of his bastard brother, who is generally known in history as Genseric, though the more correct form of his name is Gaiseric. This man, short of stature and with limping gait, but with a great natural capacity for war and dominion, reckless of human life and unrestrained by conscience or pity, was for fifty years the hero of the Vandal race and the terror of Constantinople and Rome. Probably in the month of May 428 he assembled all his people on the shore of Andalusia, and numbering the males among them from the greybeard down to the newborn infant found them to amount to 80,000 souls. The passage was effected in the ships of Bonifacius, who, however, soon returning to his old loyalty, besought his new allies to depart from Africa. They, of course, refused, and Bonifacius turned against them, too late, however, to repair the mischief which he had caused. Notwithstanding his opposition, the progress of the Vandals was rapid, and by May 430 only three cities of Roman Africa—Carthage, Hippo and Cirta—remained untaken. The long siege of Hippo (May 430 to July 431), memorable for the last illness and death of St Augustine, which occurred during its progress, ended unsuccessfully for the Vandals. At length (30th January 435) peace was made between the emperor Valentinian III. and Gaiseric. The emperor was to retain Carthage and the small but rich proconsular province in which it was situated, while Hippo and the other six provinces of Africa were abandoned to the Vandal. Gaiseric observed this treaty no longer than suited his purpose. On the 19th of October 439, without any declaration of war, he suddenly attacked Carthage and took it. The Vandal occupation of this great city, the third among the cities of the Roman empire, lasted for ninety-four years. Gaiseric seems to have counted the years of his sovereignty from the date of its capture. Though most of the remaining years of Gaiseric's life were passed in war, plunder rather than territorial conquest seems to have been the object of his expeditions. He made, in fact, of Carthage a pirate's stronghold, whence he issued forth, like the Barbary pirates of a later day, to attack, as he himself said, "the dwellings of the men with whom God is angry," leaving the question who those men might be to the decision of the elements. Almost alone among the Teutonic invaders of the empire he set himself to form a powerful fleet, and was probably for thirty years the leading maritime power in the Mediterranean. Gaiseric's celebrated expedition against Rome (455), undertaken in response to the call of Eudoxia, widow of Valentinian, was only the greatest of his marauding exploits. He took the city without difficulty, and for fourteen days, in a calm and business-like manner, emptied it of all its movable wealth. The sacred vessels of the Jewish temple, brought to Rome by Titus, are said to have been among the spoils carried to Carthage by the conqueror. Eudoxia and her two daughters were also carried into captivity. One of the princesses, Eudocia, was married to Hunneric, eldest son of Gaiseric; her mother and sister, after long and tedious negotiations, were sent to Constantinople.

There does not seem to be in the story of the capture of Rome by the Vandals any justification for the charge of wilful and objectless destruction of public buildings which is implied in the word "vandalism." It is probable that this charge grew out of the fierce persecution which was carried on by Gaiseric and his son against the Catholic Christians, and which is the darkest stain on their characters. This persecution is described with great vividness, and no doubt with some exaggeration, by the nearly contemporary Victor Vitensis. Churches were burned; bishops and priests were forced by cruel and revolting tortures to reveal the hiding-places of the sacred vessels; the rich provincials who were employed about the court, and who still adhered to the Catholic faith, were racked and beaten, and put to death. The bishops were almost universally banished, and the congregations were forbidden to elect their successors, so that the greater part of the churches of Africa remained "widowed" for a whole generation. In 476, at the very close of Gaiseric's life, by a treaty concluded with the Eastern emperor, the bishops were permitted to return. There was then a short lull in the persecution; but on the death of Gaiseric (477) and the accession of Hunneric it broke out again with greater violence than ever, the ferocity of Hunneric being more thoroughly stupid and brutal than the calculating cruelty of his father.

On the death of Hunneric (484) he was succeeded by his cousin Gunthamund, Gaiseric having established seniority among his own descendants as the law of succession to his throne. Gunthamund (484–96) and his brother Thrasamund (496–523), though Arians, abated some of the rigour of the persecution, and maintained the external credit of the monarchy. Internally, however, it was rapidly declining, the once chaste and hardy Vandals being demoralized by the fervid climate of Africa and the sinful delights of their new capital, and falling ever lower into sloth, effeminacy and vice. On the death of Thrasamund, Hilderic (523–31), the son of Hunneric and Eudocia, at length succeeded to the throne. He adhered to the creed of his mother rather than to that of his father; and, in spite of a solemn oath sworn to his predecessor that he would not restore the Catholic churches to their owners, he at once proceeded to do so and to recall the bishops. Hilderic, elderly, Catholic and timid, was very unpopular with his subjects, and after a reign of eight years he was thrust into prison by his warlike cousin Gelimer (531–34).

The wrongs of Hilderic, a Catholic, and with the blood of Theodosius in his veins, afforded to Justinian a long-coveted pretext for overthrowing the Vandal dominion, the latent weakness of which was probably known to the statesmen of Constantinople. A great expedition under the command of Belisarius (in whose train was the historian Procopius) sailed from the Bosporus in June 533, and after touching at Catana in Sicily finally reached Africa in the beginning of September. Gelimer, who was strangely ignorant of the plans of Justinian, had sent his brother Tzazo with some of his best troops to quell a rebellion in Sardinia (that island as well as the Balearic Isles forming part of the Vandal dominions), and the landing of Belisarius was entirely unopposed. He marched rapidly towards Carthage and on the 13th of September was confronted by Gelimer at Ad Decimum, 10 m. from Carthage. The battle did not reflect any great credit either on Byzantine or Vandal generalship. It was in fact a series of blunders on both sides, but Belisarius made the fewest and victory remained with him. On the 14th of September 533 the imperial general entered Carthage and ate the feast prepared in Gelimer's palace for its lord. Belisarius, however, was too late to save the life of Hilderic, who had been slain by his rival's orders as soon as the news came of the landing of the imperial army. Still Gelimer with many of the Vandal warriors was at liberty. On the return of Tzazo from Sardinia a force was collected considerably larger than the imperial army, and Gelimer met Belisarius in battle at a place about 20 m. from Carthage, called Tricamarum (December 533). This battle was far more stubbornly contested than that of Ad Decimum, but it ended in the utter rout of the Vandals and the flight of Gelimer. He took refuge in a mountain fortress called Pappua on the Numidian frontier, and there, after enduring great hardships in the squalid dwellings of the Moors, surrendered to his pursuers in March 534. The well-known stories of his laughter when he was introduced to Belisarius, and his chant, "Vanitas vanitatum," when he walked before the triumphal car of his conqueror through the streets of Constantinople, probably point to an intellect disordered by his reverses and hardships. The Vandals who were carried captive to Constantinople were enlisted in five squadrons of cavalry and sent to serve against the Parthians under the title "Justiniani Vandali." Four hundred escaped to Africa and took part in a mutiny of the imperial troops, which was with difficulty quelled by Belisarius (536). After this the Vandals disappear from history. The overthrow of their kingdom undoubtedly rendered easier the spread of Saracen conquest along the northern shore of Africa in the following century. In this as in many other fields Justinian sowed that Mahomet might reap. (T. H.)

See Pliny, *Natural History*, iv. 99; Tacitus, *Germania*, cc. 2, 43; Ptolemy, ii. c. 11, §§ 18 ff.; Julius Capitolinus, *De Bello Marcomannico*, 17; Vopiscus, *Probus*, 18; Dexippus, *Excerpta*, pp. 19 ff. (Bonn); and Jordanes, 4, 16, 22; Procopius, *De Bello Vandalico*, a first-rate authority for contemporary events, must be used with caution for the history of the two or three generations before his time. The chroniclers Idatius, Prosper and Victor Tunnunensis supply some facts, and for the persecution of the Catholics Victor Vitensis and the *Vita Augustini* of Posidius may be consulted. See also E. Gibbon, *Decline and Fall*, chaps. xxxiii. and xli.; Papencordt, *Geschichte der vandalischen Herrschaft in Afrika* (Berlin, 1837); T. Hodgkin, *Italy and her Invaders* (1880–99); L. Schmidt, *Geschichte der Wandalen* (Leipzig, 1901); and F. Martroye, *L'Occident à l'époque byzantine* (1904).

VANDAMME, DOMINIQUE RENÉ, Count (1770–1830), French soldier, was born at Cassel, near Dunkirk, on the 5th of November 1770. He enlisted in the army in 1786, served in Martinique in 1788 and on returning to France entered into the Revolutionary movement, raising a company of light infantry at his native place. His extraordinary bravery and vigour in the campaign of 1793 ensured his rapid promotion, and after Hondschoote he was made a general of brigade. He served in this rank in the campaigns of 1794 in the Low Countries, 1795 on the Rhine and 1796 in Germany, and at the outbreak of the war in 1799 he was promoted general of division. In that year and in 1800 he served under Brune, Moreau and Macdonald in Holland, Germany and Switzerland. He was renowned for his tenacity and fearlessness as a fighting general as well as for his frank, rough manners and plundering and dissolute life, but once he came under Napoleon's influence he was (unlike most of the Rhine Army officers) his absolutely devoted servant. In 1805, for his splendid leadership at Austerlitz, he was given the Grand Eagle of the Legion of Honour, and in 1806–7 he commanded a small corps of the *Grande Armée* which reduced the Silesian fortresses. In 1808 he was made count of Unebourg. In 1809 he served in the Eckmühl campaign with distinction, but in 1812, while commanding the Westphalian contingent he quarrelled with King Jerome Bonaparte and returned to France. He returned to the army in 1813. But his corps, sent against the line of retreat of the Allies at the time of the battle of Dresden, was entangled in the mountains, surrounded and after a fierce resistance compelled to surrender at Kulm (see Napoleonic Campaigns). In his captivity he appears to have been treated with especial harshness, and when the end of the war released him he was forbidden to enter Paris, and sent to Cassel by Louis XVIII. He was thus free of all obligations towards the Bourbons, and when Napoleon returned, joined him without hesitation. The emperor made him a peer of France and placed him at the head of the III. corps in the Army of the North (see Waterloo Campaign). After Waterloo, under Grouchy's command, he brought back his corps in good order to Paris and thence to the Loire. The Restoration first imprisoned and then exiled him, and unlike most of his comrades he was never re-employed as a general. He died at Cassel on the 15th of July 1830.

VANDERBILT, CORNELIUS (1794–1877), American capitalist, was born near Stapleton, Staten Island, New York, on the 27th of May 1794. He was a descendant of Jan Aersten Van der Bilt, who emigrated from Holland about 1650 and settled near Brooklyn. The family removed to Staten Island in 1715. At the age of 16 he bought a sailboat, in which he carried farm produce and passengers between Staten Island and New York. He was soon doing a profitable carrying business, and in 1813 carried supplies to fortifications in New York Harbour and the adjacent waters. Recognizing the superiority of steam over sailing vessels, he sold his sloops and schooners, and in 1817–1829 was a captain on a steam ferry between New York and New Brunswick. During the next twenty years he developed an extensive carrying trade along the coast in a fleet which became so large as to win for him the popular designation of "Commodore." In 1849 he got from the Nicaraguan government a charter for a route from Greytown on the Atlantic by the San Juan river and Lake Nicaragua to San Juan del Sur, on the Pacific; and in 1851–1853 by means of this route he conducted a semi-monthly steamship line between New York and San Francisco. In 1855–1861 he operated a freight and passenger line between New York and Havre, and by carrying the United States mails free drove out of business his only rival, the Collins line—the Cunard boats being at that time in use for the Crimean War. In 1857–1862 he sold his steamships and turned his attention more and more to the development of railways. In 1857 he became a director, and in 1863 president, of the New York & Harlem railway company, operating a line between New York and Chatham Four Corners, in Columbia county, and he greatly improved this service. He then acquired a controlling interest in the Hudson River railway, of which he became president in 1865; and after a sharp struggle in 1868 he became president of the New York Central (between Albany and Buffalo), which in 1869 he combined with the Hudson River road, under the name of the New York Central & Hudson River railroad, of which he became president. His acquisition of the Lake Shore & Michigan Southern railway in 1873 established a through line (controlled by him) between New York and Chicago. At the time of his death (in New York City on the 4th of January 1877) he owned a majority interest in the New York Central & Hudson River, the Lake Shore & Michigan Southern, the Harlem, and the Canada Southern railways, and had holdings in many others, and his fortune was variously estimated at from $90,000,000 to $100,000,000, about $80,000,000 of which he left to his son, William Henry. He made considerable benefactions to Vanderbilt University, and gave $50,000 during his life to the Church of the Strangers in New York.

His eldest son, William Henry Vanderbilt (1821–1885), was born in New Brunswick, New Jersey, on the 8th of May 1821. He was a clerk in a New York banking house from 1839 to 1842, when his father bought him a farm of 75 acres near New Dorp, Staten Island, New York. In 1860 he was appointed receiver of the Staten Island railway, of which he was elected president in 1862, and which he brought into connexion with New York by means of a line of ferry-boats. He became vice-president of the Hudson River railway in 1865, vice-president of the New York Central & Hudson River railway in 1869, and president in June 1877, succeeding his father as president of the Lake Shore & Michigan Southern, the Canada Southern, and the Michigan Central railways. He died in New York on the 8th of December 1885. His fortune at the time of his death was estimated at $200,000,000. In 1880 he paid all the expenses ($100,000) incident to the removal of the obelisk ("Cleopatra's Needle") from Egypt to Central Park, New York; in the same year he gave $100,000 to found the Theological School of Vanderbilt University, which his father had endowed. In 1884 he gave $500,000 to found a school of medicine in connexion with the College of Physicians and Surgeons in New York. By his will he left $200,000 to Vanderbilt University, $100,000 to the Domestic and Foreign Missionary Society of the Protestant Episcopal Church, $100,000 to St Luke's Hospital in New York, $100,000 to the Young Men's Christian Association of New York, $100,000 to the Metropolitan Museum of Art in New York, $5c,000 to the American Museum of Natural History, $100,000 to the Protestant Episcopal Mission Society of New York, and $250,000 in all to various other religious and charitable organizations and institutions.

William Henry's eldest son, Cornelius (1843–1899), became assistant treasurer of the Harlem railway in 1865, and treasurer in 1867; in 1877, after the death of his grandfather, was elected first vice-president of the New York Central, and in 1878 became treasurer of the Michigan Central and vice-president and treasurer of the Canada Southern. In 1883, under a reorganization of the New York Central and Michigan Central railways, he became chairman of the boards of directors of those two systems and their responsible head. His benefactions included $250,000 (1897) for an addition to St Bartholomew's Hospital in New York; to Yale, $1,500,000, part of which was used in building Vanderbilt Hall (a dormitory); and $100,000 to the fund for the building of the Episcopal Cathedral of St John the Divine in New York. To the Metropolitan Museum of Art in New York he presented Rosa Bonheur's "Horse Fair."

(Cleveland, Ohio, 1888); and Burton J. Hendrick, "The Vanderbilt Fortune," in *McClure's Magazine*, vol. xxxii. (New York, 1908–1909).

VANDERLYN, JOHN (1776–1852), American artist, was born at Kingston, New York, on the 15th of October 1776. He was employed by a print-seller in New York, and was first instructed in art by Archibald Robinson (1765–1835), a Scotsman who was afterwards one of the directors of the American Academy. He copied some of Gilbert Stuart's portraits, including one of Aaron Burr, who placed him under Gilbert Stuart as a pupil. In 1796 Vanderlyn went to Paris, and in 1805 to Rome, where he painted his picture of "Marius amid the Ruins of Carthage," which was shown in Paris, and obtained a gold medal there. This success caused him to remain in Paris for seven years, during which time he prospered greatly. In 1812 he showed a nude "Ariadne" (engraved by Durand, and now in the Pennsylvania Academy), which increased his fame. When Aaron Burr fled to Paris, Vanderlyn was for a time his only support. Vanderlyn returned to America in 1815, but did not meet with success; he worked very slowly, and neither his portraits nor various panorama which he exhibited brought him any considerable financial return. In 1842, through friendly influences, he was commissioned by Congress to paint "The Landing of Columbus" for one of the panels in the rotunda of the Capitol at Washington. Going to Paris, he employed to assist him a French artist, who, it is said, did most of the work. He died in absolute want at Kingston, New York, on the 23rd of September 1852. Vanderlyn was the first American to study in France instead of in England, and to acquire accurate draughtsmanship. He was more academic than his fellows; but, though faithfully and capably executed, his work was rather devoid of charm. He painted portraits of Presidents Washington (a copy of Stuart's portrait, for the National House of Representatives), Monroe, Madison, Jackson and Taylor, and of the statesmen Robert R. Livingston (New York Historical Society), John C. Calhoun and George Clinton.

VAN DER STAPPEN, CHARLES (1843–1910), Belgian sculptor, was born in Brussels, September 1843. His first contribution to the Brussels Salon was "The Faun's Toilet" of 1869, and thereafter he began to produce work of a high and novel order in every class of sculpture, and soon, along with Paul de Vigne, became recognized as the leader of the section of the new Belgian school of sculpture which, while aiming at truth to life, allowed itself nevertheless to be inspired by the classic perfection of the art of Greece and the spirit of the Italian Renaissance. Van der Stappen has shown his greatest power in decorative sculpture, such as we see in the decoration on the Palais des Postes, Brussels (1872), as well as the pediment "Orchestration" for the Conservatoire de Musique, and the noble bronze group, "The Teaching of Art," on the façade of the Palace of Fine Arts, Brussels. Among his other decorative work are the statues for the Alhambra Theatre and the caryatides for the house of the architect M. de Curté (1874). His best-known monuments are those to "Alexandre Gendebien" (1874) and "Baron Coppens," at Sheel (1875). His statues include "William the Silent," set up in the Square du Petit Sablon, "The Man with the Sword," and "The Sphinx"—the last two in the Brussels Museum. The bronze group "Ompdrailles" was acquired by the Belgian government (1892). In 1893 the sculptor began his collaboration with Constantin Meunier for the elaborate decoration of the botanical gardens of Brussels, and the result of the connexion may be seen in "The Builders of Cities," a group which might almost have come from his companion, so strongly is it imbued with the sentiment and illustrative of the types of the "socialistic art" of Meunier.

See *Charles van der Stappen*, by Camille Lemonnier; *Les Artistes belges contemporains*, by E. L. de Taye; *The Renaissance of Sculpture in Belgium*, by O. G. Destrée (London, 1895).

VAN DER WEYDEN, ROGER (*c.* 1400–1464), Flemish painter, also known as Roger de la Pasture, Rogier de Bruxelles, &c., was born at Tournay, where in 1427 he entered the studio of Robert Campin. He established himself in Brussels about 1435. He was in Italy in 1449–1450, but his visit shows no result on his style, which owes nothing to Italian models; and he returned to Brussels, where he died on the 18th of June 1464. His vigorous, subtle and expressive painting and popular religious conceptions had considerable influence on the art of Flanders and Germany. Memlinc was his greatest pupil; and his place in the early Flemish school is second only to that of the Van Eycks. He was not a pupil of Jan van Eyck, as was at one time supposed. His principal paintings were: a "Descent from the Cross" (1440), now in Madrid, and another (1443) in the church of St Pierre at Louvain; a triptych (1438–1440), now in the Berlin Museum; "Madonna with Saints" (1450), at the Städel Institute, Frankfort; a "Last Judgment" (1451), in the hospital of Beaune, France; the portraits of Philip the Good (Antwerp Museum) and Charles the Bold (Brussels Museum), painted about 1456–1458; the "Altar-piece of St John" and the triptych from Middelburg (Berlin Museum); an "Entombment of Christ" (National Gallery); a "Woman Crying" (Brussels Museum); "Descent from the Cross" (Louvre); "Adoration of the Magi" (Old Pinakothek at Munich); "Descent from the Cross" (the Hague); "Seven Sacraments" (Antwerp Museum); "Descent from the Cross" (Brussels Museum). Some of these latter, and others, are only doubtfully attributed to the master. The "Crucifixion" in the Brussels Museum, assigned either to him or to Memlinc, and containing portraits of the Sforzas, probably represents Roger van der Weyden in some of the principal figures at least, though Memlinc may have completed the picture.

There was a younger Roger van der Weyden (*c.* 1450–1529), to whom a brilliant "Mary Magdalen" in the National Gallery is attributed.

There are Lives of the elder Van der Weyden by A. Wauters (1856) and Alex. Pinchart (1876).

VANDEVELDE, ADRIAN (1639–1672), Dutch animal and landscape painter, a brother of William Vandevelde (*q.v.*), the marine painter, was born at Amsterdam in 1639. He was trained in the studio of Jan Wynants, the landscape painter, where he made the acquaintance of Philip Wouwerman, who is believed to have aided him in his studies of animals, and to have exercised a powerful and beneficial influence upon his art. Having made exceptionally rapid progress, he was soon employed by his master to introduce figures into his landscape compositions, and he rendered a similar service to Hobbema, Ruysdael, Verboom and other contemporary artists. His favourite subjects are scenes of open pasture land, with sheep, cattle and goats, which he executed with admirable dexterity, with much precision of touch and truth of draughtsmanship, and with clear silvery colouring. He painted a few small but excellent winter scenes with skaters, and several religious subjects, such as the "Descent from the Cross," for the Roman Catholic church in Amsterdam. In addition to his paintings, of which nearly two hundred have been catalogued, he executed about twenty etchings, several of which appear from their dates to have been done in his fourteenth year. They are simple but pleasing in tonality, and are distinguished by great directness of method and by delicacy and certainty of touch. Adrian Vandevelde died at Amsterdam in January 1672.

VANDEVELDE, WILLIAM (1633–1707), the younger, Dutch painter, a son of William Vandevelde, the elder, also a painter of sea-pieces, was born at Amsterdam in 1633. He was instructed by his father, and afterwards by Simon de Vlieger, a marine painter of repute at the time, and had achieved great celebrity by his art before he came to London. In 1674 he was engaged by Charles II., at a salary of £100, to aid his father in "taking and making draughts of sea-fights," his part of the work being to reproduce in colour the drawings of the elder Vandevelde. He was also patronized by the Duke of York and by various members of the nobility. He died in London on the 6th of April 1707. Most of Vandevelde's finest works represent views off the coast of Holland, with Dutch shipping. His best productions are delicate, spirited and finished in handling, and correct in the drawing of the vessels and their rigging. The numerous figures are tellingly introduced, and the artist is successful in his renderings of sea, whether in calm or storm.

Vandevelde was a most prolific artist: in addition to his paintings, of which Smith catalogues about three hundred and thirty, he executed an immense number of drawings, sketches and studies, which are prized by collectors.

VAN DORN, EARL (1820–1863), American soldier, was born near Vicksburg in 1820, and entered the army of the United States from West Point in 1842. For several years previous to the Mexican War he was employed in garrison duty, but in that war he saw a good deal of active service, distinguishing himself at Cerro Gordo and Churubusco, returning to the United States a brevet-major. He also fought in the Seminole War and in 1858 against the Comanches. When his state seceded in 1861 he resigned his commission in the U.S. army, and in the September of that year became major-general C.S.A. He commanded the Confederates in the hard-fought battle of Pea Ridge, but was superseded for failing to win it. Later in 1862 he won promotion and a second independent command in the West, and led the Confederates at the battle of Corinth (the 3rd and 4th of October 1862) at which he came very near to success. In spite of the verdict of a court of inquiry, he was again superseded. As a subordinate of Lieut.-General Pemberton he did splendid service to the Confederate cause in defeating Grant's first advance on Vicksburg at Holly Springs (1862). He was shot in a private quarrel on the 8th of May 1863.

VAN DYCK, SIR ANTHONY (1599–1641), Flemish painter, was born in Antwerp on the 22nd of March 1599. Though the name of Van Dyck is frequently met with in the list of Antwerp painters, Anthony's pedigree cannot be traced beyond his grandparents, who were silk mercers of some standing. He was the seventh of twelve children of Frans Van Dyck, an Antwerp tradesman in good circumstances. His mother, Maria Cupers, who died when he was scarcely eight years of age, seems to have attained a certain degree of excellence in art needlework. Of the boy's early education nothing is known. He was little over ten when he was apprenticed to Hendrick Van Balen, the painter of many delicate little pictures as well as an occasional collaborator of Rubens and Breughel, and the master of Snyders. From a document in the state paper office at Brussels, relating to a lawsuit between a picture dealer and an Antwerp churchman, which arose out of the sale, in 1660, of a series of Apostles' heads ascribed to Van Dyck, it appears that, as far back as 1615, Van Dyck had worked independently, with pupils of his own, and that his pictures were greatly valued by artists and amateurs. Professor Woermann has identified several of the Apostles' heads here spoken of with some paintings in the gallery at Dresden. Another is in the possession of Earl Spencer at Althorp.

Before he was nineteen (February 1618) Van Dyck became a full member of the Antwerp gild of painters; and some idea of his ability at the time may be gained from the excellent portraits of an old lady and gentleman, formerly ascribed to Rubens, in the Dresden gallery. Dated 1618, they were originally entered as works of Van Dyck, and, as Professor Woermann observes, are undoubtedly the same as those spoken of by Mols in his MS. annotations on Walpole's *Anecdotes*, now in the library at Brussels. But the same admiration cannot be accorded to the earliest religious composition known to have been painted by him—"Christ falling under the Cross," in St Paul's at Antwerp. This picture, of some ten life-size figures, still preserved in the place for which it was originally destined, distinctly proves that from the outset of his career Van Dyck's power of conception was vastly inferior to his refined taste as a portrait painter. At first sight it seems also that with him, as with most other Flemish painters of the period, every conception, whether sacred or profane, needed to be cast in the mould of Rubens. It would be too much, however, to assert that Van Dyck at this time stood under the guidance of that master; their association, indeed, does not seem to have begun until 1619, and Bellori (1672), who got his information from Sir Kenelm Digby, Van Dyck's bosom friend, tells us that he was first employed in making drawings (probably also chiaroscuros) for the use of the great master's engravers, and that among works of the kind one of the first was the "Battle of the Amazons" (1619).

In 1620, we know, Van Dyck was working with Rubens, for on 20th March, in making arrangements with the Antwerp Jesuits for the decoration of their church, the master is allowed to avail himself of his pupil's assistance, and obtains for him the promise of a picture. This proof of Van Dyck's personal reputation is fully confirmed (17th July) by a correspondent of the earl of Arundel, who speaks of Van Dyck as a young man of one-and-twenty whose works are scarcely less esteemed than those of his master, and adds that, his relations being people of considerable wealth, he could hardly be expected to leave his home. Van Dyck was, however, thus persuaded, for on 28th November Sir Toby Mathew mentions the artist's departure to Sir Dudley Carleton, adding that he is in receipt of an annual pension of £100 from the king. There is evidence of Van Dyck's presence in London till the end of February 1621. He is first mentioned in the order-books of the Exchequer on the 17th of that month as receiving a reward of £100 "for special service by him performed for His Majesty," and on the 28th, "Antonio van Dyck, gent., *His Majesties servant*, is allowed to travaile 8 months, he havinge obtayneid his Ma$^{\text{ties}}$ leave in that behalf, as was signified by the E. of Arundell." What Van Dyck did in London is not known. Among his numerous paintings still preserved in English houses one only is admitted as belonging to the period of this first visit, a full-length portrait of James I. in the royal collection. That he was at the time a portrait painter of the rarest merit may easily be seen from the portrait of "Van der Geest" in the National Gallery (London), and from his own likenesses of himself when still quite young and beardless, in the National Gallery, in the Pinakothek at Munich and in the Wallace Collection. In this last admirable specimen the young painter has represented himself in the character of Paris. Early paintings by Van Dyck are certainly not scarce in British galleries; at Dulwich there is his admirable Samson and Delilah, ascribed to the school of Rubens.

Though the leave of absence was probably obtained by Van Dyck for the purpose of studying the masters in Italy, the eight months had almost elapsed before he started from Antwerp, whither he had gone from London. He left Antwerp on the 3rd of October 1621, and arrived at Genoa on the 21st of November of the same year. Though Van Dyck unquestionably first became acquainted with the masterpieces of the great Venetian colourists in Rubens's *atelier*, there can be little doubt that most of the pictures which were formerly ascribed to his earliest period really date from the years of his Italian journey. In fact, studies for some of them can be found in the Chatsworth sketch-book. Among these early works are the "Martyrdom of St Peter" (Brussels), the "Crowning with Thorns" (Berlin), the "Betrayal of Christ" (Madrid and Lord Methuen), "St Martin dividing his Cloak" (Windsor Castle),—a magnificent production, generally ascribed to Rubens, but easily identified through Van Dyck's admirable sketch at Dorchester House.

It is unnecessary to dwell on a number of tales connected with Van Dyck's early life, all of which have on closer examination proved to be apocryphal; but one story has been too frequently told to be altogether ignored. At the very outset of his Italian journey the inflammable youth was captivated by the beauty of a country girl, and for the love of her painted the altar-piece still to be seen in the church at Saventhem, near Brussels, in which he himself is supposed to be represented on a grey horse, given by Rubens to his pupil. It is now known, however, that the picture was commissioned by a gentleman living at Saventhem (to the charms of whose daughter Van Dyck in reality seems not to have been altogether insensible), and a closer study makes it almost certain that it was executed after, not before, his Italian journey. On a reduced scale, and with the omission of two or three figures, the "St Martin" at Saventhem is a reproduction of the picture at Windsor Castle.

With the exception of a short visit to Antwerp at the time of his father's death in 1622, Van Dyck spent the next five years in Italy. No master from beyond the Alps ever took up a higher position than Van Dyck among the most celebrated representatives of Italian art. Study, as a matter of course, had been one of his principal objects. No doubt can be entertained as to the great influence exerted by the works of Titian, Paul Veronese and the other great masters of the Venetian school in the development of his genius; still the individuality of the painter remains a striking feature of what may be termed his Italian works, especially portraits. Their peculiar character seems to originate even more in the stateliness of the personages he was fortunate enough to have as sitters than in any desire to follow individual predilection or prevailing fashion. As in later years Van Dyck gives us a striking picture of the higher classes in England, so at this stage he makes us acquainted with Italian beauty and style; and at no other period is his talent more advantageously shown than in some of the glorious portraits he painted at Rome, at Florence, and, above all, at Genoa. At Rome, whither he journeyed after a prolonged stay in Venice, he resided with Cardinal Guido Bentivoglio, who had been papal nuncio in Flanders from 1607 to 1617. For this patron were painted several works of very great importance, the most renowned being the prelate's own portrait, now in the Pitti Palace at Florence. Another work was a "Crucifixion," representing Christ dying on the cross with uplifted eyes. Most probably the picture spoken of by Bellori ought to be identified with the admirable canvas now in the gallery at Naples, catalogued as "Scuola di Van Dyck," unsurpassed by any of those at Antwerp, Paris, Vienna, Rome or elsewhere. Besides these he painted religious subjects and portraits, several of which are reckoned among his finest examples, such as the portrait of Duquesnoy, better known as Fiammingo, the famous sculptor, formerly belonging to the king of the Belgians, and those of Sir Robert Shirley and his wife, in Persian attire, now at Petworth.

Bellori tells us of Van Dyck's prepossessing appearance, of his elegance and distinction, altogether so different from the habits of his compatriots in Rome, who formed a jovial "gang," as they termed their association. Van Dyck seems to have kept out of their way, and incurred in consequence such annoyance as made his stay in Rome much shorter than it would otherwise have been. In the company of Lady Arundel he travelled to Turin, but he was eager to reach Genoa, where Rubens had worked with great success some twenty years before, and where his Antwerp friends, Luke and Cornelis de Wael, for many years resident in Italy, now were. Van Dyck remained their guest for several months, and their portraits, now in the Pinacoteca Capitolina at Rome (engraved by W. Hollar from the monochrome at Cassel), may be supposed to have been one of his first Genoese productions. Though several of the palaces of the "proud" city no longer retain their treasures, and, among the specimens of Van Dyck's genius still left, too many have been greatly injured by cleaning and retouching, Genoa can still boast of a good number of his most attractive productions, portraits of the beautiful ladies and haughty cavaliers of the noble houses of Doria, Brignole Sale, Pallavicini, Balbi, Cattaneo,[1] Spinola, Lommelini and Grimaldi. It would

[1] Of the Cattaneo portraits, originally eight in number, seven were privately sold out of Italy in 1906, and in the following year one, a half-length "Portrait of a Man," was acquired for the National Gallery, London, for £13,500. The official acquisition

scarcely be possible to speak too highly of such works as the portrait of the lady in white satin and the Durazzo children at the Durazzo Palace, the Balbi children at Panshanger, the Marchesa Balbi at Dorchester House, the equally beautiful portraits of the Lommelini and of the knight in black armour, buff jacket and boots in the Scottish National Gallery at Edinburgh, or the Marchesa Brignole Sale (formerly at Warwick Castle, and afterwards in America). Van Dyck's "Genoese manner" is a current expression, and indeed his Genoese portraits are remarkable for their richness of tonality and what might be called royal splendour, perhaps never before attained in works of the kind. This we may suppose to have had its origin, not only in his recent study of Titian, but also in decorative necessities—the size of the palatial galleries and the rich hues of the Genoese velvets, on which these portraits were to find their place, obliging the painter to find a most uncommon strength of contrast. It must also be acknowledged that the beauty and distinction of Van Dyck's models are greatly enhanced by a splendour of costume entirely different from the dullness then prevalent almost everywhere else. In Italy, moreover, he found the reality of those gorgeous backgrounds—flowing draperies, beautiful gardens, ornamental pillars, marble terraces and balustrades—which elsewhere must be regarded as fictions merely. Here, finally, he was for the first time called upon to paint some of his grandest equestrian portraits, and the often-recurring grey steed with flowing mane (an admirable study of which belongs to Lord Brownlow) was first employed for the portrait of Antonio Giulio Brignole (still at Genoa) and for another picture which we may suppose to represent the same personage at Stafford House. As with Rubens, Titian seems to have been paramount in Van Dyck's regard. Copies in great number we know he possessed of the master's best works, and several little sketches in the British Museum and in the Chatsworth sketch-book bear proof of his devout study of the great Venetian. Some of Van Dyck's earlier paintings, religious and mythological—the "Tribute Money" (Brignole Palace), "Holy Family" (Turin), "Virgin and Saints" (Louvre), "Virgin" (Grosvenor House), "Martyrdom of St Lawrence" (S. Maria dell' Orto, Venice), "Bacchanal" (Lord Belper)—engraved at Genoa as early as 1628—"St Sebastian" (Edinburgh)—are certainly Titianesque in the extreme. Still the master's individuality is not obliterated, and the gallery at Parma has a "Virgin with the Infant Asleep," which may be termed a marvel of realistic simplicity.

In 1624 Van Dyck sailed from Genoa to Palermo and there painted several persons of rank, including the viceroy, Emmanuel Philibert of Savoy. While in Sicily he became acquainted with the painter Sofonisba Anguisciola (or Angussola), who was then ninety-six years of age and blind; and he was wont to say that he had received more valuable information from a blind woman than from many a seeing man. No important works of Van Dyck are now to be found in Sicily, except the "Virgin and Child" at S. Caterina in Palermo, and a "Virgin and Child with Saints" in the same city. Bellori tells us that a plague broke out and compelled him to leave abruptly, taking with him an unfinished picture of St Rosalia, which was destined for a confraternity of that name, and was completed in Genoa. The composition was repeated in Antwerp for the Bachelors' Brotherhood, a picture now in Vienna. Van Dyck most probably remained in Genoa till 1626, and here in all likelihood he painted the De Jodes, father and son, the celebrated engravers, who are represented together in a masterly portrait in the Capitol at Rome, the companion picture to the brothers De Wael; and Nicholas Lanière, musician-in-chief to Charles I., a painting spoken of in Van der Dort's catalogue as "done beyond the seas." Lanière was in Italy precisely at this time, and it was through his portrait (now at Windsor Castle), Walpole assures us, that Van Dyck attracted the notice of Charles I.

Traversing the Mont Cenis pass, Van Dyck stopped at Aix with Peiresc, the famous scholar and friend of Rubens, and probably proceeded straight to Antwerp. His beautiful portrait of Langlois, the Paris print-seller, from which it was conjectured that he spent some time at Paris, was unquestionably painted in Genoa. It is very likely that, before settling again at Antwerp, Van Dyck at this time paid a second visit to England, to paint a portrait of Queen Henrietta Maria, but left again when he found Mytens firmly established as court favourite. He probably returned to Antwerp in 1627, though there is no recorded proof of his presence before the 3rd of March 1628. One of his sisters had died in a convent the year before, and he now made a will in favour of Susan and Isabella, two other sisters, also nuns. That Van Dyck was in Antwerp on the 18th of May is proved by a letter from Lord Carlisle to Buckingham (Sainsbury, ciii.).

Great as may have been the strength of Italian reminiscence, from the moment Van Dyck again trod Flemish soil the influence of Rubens became predominant, and we can scarcely doubt that a competition speedily arose between master and pupil. At this period churches and convents were numerous and richly endowed; and the number of pictures, stained glass windows and elaborate carvings in Belgian churches before the French conquest was enormous. Hardly fifty years had elapsed since these buildings had been stripped of their artistic treasures, and the devout were now eager once more to adorn them with productions of the greatest painters. Hence Van Dyck's share could be very copious without in any degree interfering with the vast undertakings assigned to Rubens. The latter was also absent for many months in 1629 and 1630, so that Van Dyck was for a time the first master in the Netherlands. Among the earliest works after his return to Antwerp we find the "Crucifixion," given to the Dominican nuns, in accordance with the wish expressed by the painter's dying father, and now in the Antwerp museum. The figures are life-size, and at the foot of the cross, besides a weeping angel, are St Catherine of Siena and St Dominic. Neither in type nor in general effect does it suggest the master's immediately preceding works. As a new feature we observe a kind of elegance, not entirely free from mannerism, which is often conspicuous with Van Dyck even when the technical excellence commands our warmest admiration. Inspiration, as Waagen observes, was far more limited with Van Dyck than with Rubens. His truly delicate nature led him to restrain his conceptions within the bounds of an academic evenness, generally more pleasing to the uninitiated than the strength of expression which sometimes imparts a sort of violence to the works of Rubens. To Van Dyck's second—more justly speaking third—manner belong some of his best religious works. The "Crucifixion" in the cathedral at Mechlin is termed by Sir Joshua Reynolds one of the finest pictures in the world. Other Crucifixions are in St Michael's at Ghent (sketches in Lord Brownlow's collection and the Brussels museum) and in the church at Termonde. Still finer are the two works painted for the Antwerp Jesuits and now at Vienna—"The Mystic Marriage of the Blessed Herman Joseph" and "St Rosalia Crowned by the Infant Saviour." To this period likewise belong the celebrated "Elevation of the Cross" at Courtrai and the "St Augustine in Ecstasy," in the church of the Jesuits at Antwerp; the general effect of this last, it must be acknowledged with Reynolds, is inferior to that of the beautiful engraving by De Jode, and also to the earl of Northbrook's magnificent sketch. At Dulwich we find the first idea of the composition, with many interesting differences. It may be a matter of individual preference to pronounce Van Dyck's Flemish portraits superior to those of an earlier period; but nobody can fail to admit that, technically speaking, they indicate a further step towards perfection. The darkness of the Genoese portraits has vanished; broad daylight now freely illuminates the model, and such works as the portraits of Francisco de Moncada (Louvre) and of the Count de Bergh (Prado) are perhaps as close to material excellence as any painting could be. The full-length likenesses of Philip Le Roy (1630) and his wife

of this picture, in view of the Italian law of 1902, created considerable discussion in Italy and England. The companion female portrait was soon after also purchased.

(1631) (Wallace Collection) and of Mary Louisa of Tassis (Prince Liechtenstein, Vienna) are not only the finest examples of the master's talent, but deserve to rank among the most beautiful portraits ever painted. The "Snyders" at Castle Howard is regarded by Waagen as not inferior to the most celebrated Raphaels, Titians or Holbeins; and of almost equal excellence are the "Wife of Colin de Nole" in the Munich gallery, the "Lady and her Daughter" at the Louvre, and the "Lady in Black" at Cassel.

Rapidly rising to honour and wealth, Van Dyck shared with Rubens the official title of court painter, and his numerous portraits of the infanta in her monastic garb (Paris, Vienna, Turin, Parma, &c.) bear testimony to the great favour in which he stood with her. When Marie de Medicis, after her flight from France, took up her residence in Brussels (1631), she honoured Van Dyck, as well as Rubens, with repeated visits, and several times called upon him to paint her likeness, as well as those of Gaston of Orleans and his wife Margaret of Lorraine, and several of the personages of their court. From Gerbier's letters we learn that Van Dyck at this time was contemplating another journey to England, and was very anxious to be commissioned by the infanta and the queen of France to take over their portraits as presents for the king and royal family. He soon travelled to the Hague to paint the prince and princess of Orange and their son. Quite at the beginning of 1632 Constantine Huygens, who was then living at the Hague, inscribes in his diary, "Pingor a Van Dyckio." When, towards the end of March, Van Dyck sailed for England, he took all these portraits with him, as we learn from an account of the 8th of August 1632 (Carpenter's *Pictorial Notices*). Dutch authors speak of a visit paid by Van Dyck to Frans Hals at Haarlem, and of a portrait of the latter through which the Antwerp master was at once recognized by his Dutch colleague. An engraving of a portrait of Hals after Van Dyck seems to confirm the story.

In undertaking this new journey to London, Van Dyck was assured of success, for Gerbier's letters show that the king had personally desired his presence. As early as March 1629 Endymion Porter, one of the gentlemen of the king's bedchamber, had been commissioned to order a picture from Van Dyck, "Rinaldo and Armida." The canvas, now belonging to the duke of Newcastle, may be looked upon as one of the master's finest creations. Exceptional favours were bestowed upon Van Dyck almost from the day of his arrival in London. Besides the title of painter in ordinary, and the grant of an annual pension of £200, he received the honour of knighthood after a residence of less than three months at court (5th July 1632). He rapidly achieved popularity among the higher classes, and, as Walpole says, his works are so frequent in England that to most Englishmen it is difficult to avoid thinking of him as their countryman.

His refined nature is strikingly illustrated in his admirable interpretation of English beauty and style. And, if Van Dyck be compared to Mytens and Cornelius Janssen, the most distinguished painters employed by the English court immediately before him, few artists, whether in England or elsewhere, have more richly endowed their models with distinction of feature and elegance in bearing. To him may be applied what Opie says of Titian, "that he combines resemblance with dignity, costume with taste, and art with simplicity." We are particularly struck with the thorough and immediate identification of his talent with local tastes and exigencies. Charles I. and Henrietta Maria, although pictured by several other painters, are known to posterity almost exclusively through Van Dyck, not from a greater closeness of resemblance to the original, but from a particular power of expression and bearing which, once seen, it is impossible to forget. The artist was lodged at the expense of the crown, with a summer residence at Eltham Palace, and was frequently honoured with the visits of the king at his studio at Blackfriars. Portraits now followed each other with a rapidity scarcely credible to those unacquainted with the artist's method. In fact, his mode of living and his love of pleasure sufficiently explain his great need of money. During the first year of his presence in England he painted the king and queen a dozen times. The first of these noble portraits is the admirable full-length of Charles I., with the queen and their two eldest children, at Windsor Castle. The style he adopted in England is generally termed his third manner; we might better say his fourth, as he already had a very particular style before he set out on his Italian journey. De Piles gives us some account of Van Dyck's methods at this period of his career. He began with a small sketch on grey paper with black and white chalks, or a monochrome in oils. This study was passed on to assistants in order to be copied on the required scale. When the clothes were sufficiently advanced by the pupils from those sent by the model, as well as the background and accessories, the master was enabled in a few sittings of an hour each to complete the work. Van Dyck excelled in painting the hands; he is said to have kept special models for this part of his work. It need hardly be said that a system of this kind, although employed by Rubens for his larger creations, was exceedingly ill adapted to portrait painting. In Van Dyck's later productions we too often detect marks of haste, as if the brush were becoming a mere implement of trade.

Nearly the whole of 1634 and 1635 were spent by Van Dyck in the Netherlands, whence his brother, an Antwerp priest, had been called over by the queen to act as her chaplain. The archduchess died on 1st December 1633, and Van Dyck naturally wished to get his official title renewed by her successor, Ferdinand of Austria, brother of Philip IV. That Van Dyck's residence in Antwerp was only to be temporary is shown by the power given to his sister Susan for the administration of his affairs in Belgium (14th April 1634). On the arrival of the new governor Van Dyck was immediately called upon to paint his likeness, a picture now in the Madrid gallery, where the same personage is also represented by Rubens and Velazquez. Several other portraits of Ferdinand, either in his cardinal's robes or in military dress, by Van Dyck, occur elsewhere. One on horseback was exhibited at the Grosvenor Gallery, London, in 1887, as the duke of Alva (lent by Mr S. Kynaston Mainwaring). Van Dyck was greatly in demand at this time, and his prices were correspondingly high, as the Antwerp municipality found when they asked for a portrait of the late infanta to decorate one of the triumphal arches for the reception of the new governor. The most important of Van Dyck's works, at any rate as a portrait painter, belong to this period. The picture representing in life-size the members of the Brussels corporation, which was destroyed by fire during the siege of 1695, is spoken of with intense admiration by several writers. Bullart, for instance, is very enthusiastic about its fine colour and lifelike qualities. Among the religious paintings of undisputed excellence belonging to the same period are the "Adoration of the Shepherds" in the church at Termonde, and the "Deposition," where the body of Christ rests upon the lap of the Virgin, in the Antwerp museum. Among the portraits are the admirable full-length of Scaglia, the king's frequent agent in the Netherlands (at Dorchester House; a replica in the museum at Antwerp), the equestrian portrait of Albert of Arenberg (Arenberg Palace at Brussels), and a portrait of the same nobleman on foot, in the black velvet Spanish dress with golden chamberlain's key (long said to be Rubens) at Althorp, the full-length of Helena Fourment, Rubens's second wife (at St Petersburg), the beautiful duchess of Havre, Mary Clara de Croy, signed and dated 1634 (Mr Ayscough Fawkes), and other members of the same family (at Munich), Thomas of Savoy (at Berlin), an admirable half-length of a lady in black (in the Vienna gallery), and above all the grandiose picture in which John of Nassau is represented at full-length, with his wife and children (at Panshanger). Several portraits of Brussels and Antwerp magistrates must also be mentioned, the most important being John Van Merstraeten, a Brussels lawyer (at Cassel).

After being chosen honorary president of the Antwerp gild of St Luke, Van Dyck returned to London before the end of 1635. In spite of the vast number of his later portraits, some of them deserve to be ranked among the most celebrated of his productions. The group of three English royal children in the gallery at Turin (1635), the portraits of Charles I. in the Louvre and in the National Gallery, London, the picture of the Pembroke family at Wilton House, Sir George and Sir Francis Villiers, and the earls of Bristol and Bedford, at Althorp, as well as those of Francis Russell, fourth earl of Bedford, and Anne Carr, his consort, at Woburn Abbey (1636), all belong to the years immediately following the master's return from the Netherlands.

He now married Lady Mary Ruthven, daughter of Sir Patrick Ruthven and granddaughter of the earl of Gowrie. There are several portraits of her by her husband, the most important being in the Munich gallery, in which she is represented in white satin, playing on the violoncello. She is also said to figure as the Virgin in a picture belonging to Lord Lyttelton. There is a capital engraving of her by Bolswert. In another picture, said to be Mary Ruthven, an exceedingly handsome lady is represented as "Herminia Putting on Clarinda's Armour." There can be no doubt as to the model having been Margaret Lemon, a celebrated beauty, whose portrait was engraved by W. Hollar and J. Morin and painted by Van Dyck at Hampton Court. "She was," says Mr Ernest Law, in his excellent catalogue of this gallery, "the most beautiful and celebrated, though far from being the only mistress of Van Dyck. The great artist, in fact, loved beauty in every form, and found the seduction of female charms altogether irresistible. She lived with him at his house at Blackfriars." The precise date of Van Dyck's marriage has not been ascertained. It was probably towards the end of 1639. The union is said to have been promoted by the artist's friends in order to save him from the consequence of his pernicious way of living. Margaret Lemon resented the event most cruelly, and tried to maim Van Dyck's right hand.

Van Dyck found few occasions in England to paint anything but portraits. There exists at Belvoir Castle a sketch by him representing a procession of the knights of the Garter, a really grandiose composition, engraved by Cooper. We know from Bellori that Van Dyck had suggested, through his friend Sir Kenelm Digby, for the banqueting-room at Whitehall, a series of decorations illustrating the history of the order of the Garter, and that the king had been much pleased with the idea. The plan, however, failed through the excessively high price asked by the painter, and perhaps also because the king had thought of having the work done in tapestry. Van Dyck's pension was five years in arrear, and, instead of £560, he received finally, besides his pension, only £200.

When the news of Rubens's death reached London (June 1640) Van Dyck contemplated a return to his native country, and a letter from Ferdinand of Austria to Philip IV. speaks of his intended journey to Antwerp on St Luke's Day (18th October). Rubens had left unfinished a series of paintings commanded by the king of Spain, and from correspondence published by Professor Justi we learn that Van Dyck had been thought of to give them the finishing touch. But he absolutely refused to finish them. It was then agreed that he should paint an independent canvas destined to complete the series. Van Dyck was delighted with this order, and Ferdinand tells his brother that he returned to London in great haste "to make preparations for his change of residence; possibly," adds the letter, "he may still change his mind, for he is stark mad." Whether Van Dyck found it possible to work during his short stay in the Netherlands is a matter of doubt. Most authors suppose that Van Dyck's principal object in travelling to the continent was to be entrusted with the decoration of one of the galleries of the Louvre. There may be some truth in this, for Mariette speaks of a letter he saw, written by Claude Vignon, the French painter, in January 1641, asking Langlois for an introduction to Van Dyck, who was then in Paris. Unfortunately the great painter was thwarted in his aspirations. His health was beginning to fail. After his return to London he was frequently obliged to interrupt his work; and a letter written (13th August) from Richmond by Lady Anne Roxburgh to Baron W. van Brederode at the Hague states that the portraits of the Princess Mary had been greatly delayed through Van Dyck's illness, and that the prince's (William II. of Orange) would be ready in eight days. "As Van Dyck intends leaving England in the course of ten or twelve days at latest," she adds, "he will take the paintings himself to the princess of Orange." These portraits, now in the museum at Amsterdam, are the last Van Dyck painted in England. Of works dated 1639 the portrait of Lady Pembroke, in the gallery of Darmstadt, is a fine example; and to the same year belongs a full-length portrait of Arthur Goodwin at Chatsworth. The twin portrait of Thomas Carew and Thomas Killigrew, in the royal collection, dated 1638, is certainly most delicate, but very weak in tone and slight in handling. Van Dyck sailed in September, and probably spent some time with his Antwerp friends. Early in November he reached Paris, and succeeded in obtaining some important work, when, on 16th November, he was compelled to resign his commissions on account of the state of his health. Scarcely three weeks later (9th December 1641) he died at his residence at Blackfriars. Van Dyck was buried in old St Paul's, where a Latin inscription was placed on his tomb by Charles I.

An elegy in Cowley's *Miscellanies* speaks, not only of the painter's talent, but of his amiable disposition. We may perhaps point to the coincidence that a Mrs Cowley is in Van Dyck's will (of 1st December) named guardian of his child, Justiniana Anna, born only eight days before her father's death. The painter had in the Netherlands an illegitimate daughter, Maria Theresia, who was entrusted to his sister, and to whom he bequeathed £4000. The name of her mother is not known. Not long after her husband's death Lady Van Dyck became the second wife of Sir Richard Pryse of Gogerddan in Cardiganshire. She was dead in 1645. Justiniana Van Dyck, who was married when scarcely twelve years old to Sir John Stepney of Prendergast, was also something of an artist: she painted a "Crucifixion," with four angels receiving Christ's blood in chalices. A similar subject had been painted by Van Dyck, as Bellori tells us, for the duke of Northumberland. After the Restoration a pension of £200 for life was granted to Justiniana Van Dyck, who died before 1690.

Properly speaking, Van Dyck cannot be said to have formed a school. He was followed to London by some of his earlier collaborators, and there soon met a considerable number of others. Jan van Reyn, David Beck, Adrian Hanneman, Mathew Merian, John Bockhorst (Lang Jan), Remy van Leemput and Peter Thys were foremost among foreigners, Henry Stone and William Dobson among Englishmen. To their assistance the master owed much; but they are also responsible for the vast number of constantly recurring copies which go by his name. It often requires a very discriminating eye to distinguish some of these copies from the original paintings. Nevertheless, after Van Dyck's death many of his coadjutors produced works of undeniable merit. No school more strikingly reflects the influence of Van Dyck than the British school. Stone and Dobson were, properly speaking, the most fortunate of his continuators; and there is little doubt that such masters as Reynolds, Gainsborough, Lawrence and Raeburn owe a large measure of their superiority to their study of his works.

Though Van Dyck's reputation greatly suffered through the numerous copies he allowed his pupils to take from his works, the case is otherwise with engraving: Vorsterman, Pontius, Peter de Jode, P. Balliu and S. Bolswert were seldom more fortunate than when under his guidance. De Jode's "St Augustine," Bolswert's "Ecce Homo" and "Crucifixion," Vorsterman's "Deposition," and especially Pontius's "Herman Joseph" rank among the masterpieces of the art of engraving. Van Dyck was himself an incomparable etcher, and with the needle arrived at a degree of excellence scarcely inferior to that exhibited in his paintings. Such prints as the portraits of Vorsterman, John de Wael, Snyders, Josse de Momper, Adam van Noort, and above all his own effigy, bear witness to his prodigious knowledge of design. Print collectors pay extravagant prices for a first proof taken from the plates engraved by Van Dyck himself. Van Dyck also employed some of the best engravers of his time for the production of a gallery of illustrious heads, men and women, of different countries. Whether all were taken from life is questionable. Gustavus Adolphus and Wallenstein he can hardly have met. Du Breucq, the architect, he never knew. But all the sketches and drawings were done by himself, and are often met with in public and private galleries. The engravings are sometimes very beautiful and in their first states very rare. Published successively by Martin van der Enden, Giles Hendrickx and John Meyssens, the collection originally consisted of sixteen warriors and statesmen, twelve scholars and fifty-two artists. Hendrickx raised the number to ninety-nine, and used as a frontispiece the portrait of Van Dyck, with the following inscription: *Icones principum, virorum doctorum, &c. &c., numero centum ab Antonio Van Dyck pictore ad vivum expressae eiusq. sumtibus aeri incisae*, 1645. Seventeen editions were published, the last in 1759, with 124 plates. Many of the plates are the property of the French Government, and belong to the Chalcographie Nationale in Paris.

LITERATURE.—See W. Hookham Carpenter, *Pictorial Notices, consisting of a Memoir of Sir Anthony Van Dyck, with a descriptive catalogue of the etchings executed by him* (London, 1844); John Smith, *A Catalogue Raisonné of the Works of the most Eminent Dutch, Flemish, and French Painters*, part iii. (London, 1841); J. Guiffrey, *Antoine Van Dyck, sa vie et son œuvre* (Paris, 1882); A. Michiels, *Ant. Van Dyck et ses élèves* (Paris, 1881); Ign. von Szwykowski, *A. VANE, SIR HENRY (1589–1654), English secretary of state, eldest son of Henry Vane or Fane, of Hadlow, Kent, a member of an ancient family of that county, by his second wife, Margaret, daughter of Roger Twysden of East Peckham, Kent, was born on the 18th of February 1589. He matriculated from Brasenose College, Oxford, on the 15th of June 1604, was admitted to Gray's Inn in 1606, and was knighted by James I. on the 3rd of March 1611. He purchased several offices at court, was made comptroller of the king's household about 1629, and in spite of a sharp quarrel with Buckingham managed to keep the king's favour, in 1639 becoming treasurer. He was returned to parliament in 1614 for Lostwithiel, from 1621 to 1626 for Carlisle, in 1628 for Retford, and in the Short and Long Parliament, assembled in 1640, he sat for Wilton. He was despatched on several missions in 1629 and 1630 to Holland, and in 1631 to Gustavus Adolphus to secure the restitution of the Palatinate, but without success. In 1630 Vane had become a privy councillor and one of the chief advisers of the king. He was made a commissioner of the Admiralty in 1632 and for the colonies in 1636. He was one of the eight privy councillors appointed to manage affairs in Scotland on the outbreak of the troubles there, and on the 3rd of February 1640, through the influence of the queen and of the marquis of Hamilton and in opposition to the wishes of Strafford, he was made secretary of state in the room of Sir John Coke. In the Short Parliament, which assembled in April, it fell to Vane, in his official capacity, to demand supplies. He proposed a bargain by which the king should give up ship-money and receive in return twelve subsidies. Parliament, however, proved intractable and was dissolved on the 5th of May, to prevent a vote against the continuance of the war with the Scots. In the impeachment of Strafford, Vane played a very important part and caused the earl's destruction. He asserted that Strafford had advised the king at a meeting of the privy council, "You have an army in Ireland; you may employ it to reduce this kingdom." He refused to admit or deny the meaning attributed by the prosecution that "this kingdom" signified England; he was unsupported by the recollection of any other privy councillor, and his statement could not be corroborated by his own notes, which had been destroyed by order of the king, but a copy obtained through his son, the younger Vane, was produced by Pym and owned by Vane to be genuine. He was on bad terms with Strafford, who had opposed his appointment to office and who had given him special provocation by assuming the barony of Raby, a title ardently desired by Vane himself. He was not unnaturally accused of collusion and treachery, and there is no doubt that he desired Strafford's removal not only on private but on public grounds, believing that his sacrifice would satisfy the demands of the parliament. Nevertheless, there has appeared no evidence to support the charge that he deliberately compassed his destruction. Suspicions of his fidelity, however, soon increased, and after having accompanied the king to Scotland in August 1641, he was dismissed from all his appointments on the 4th of November on Charles's return. Vane immediately joined the parliament; on Pym's motion, on the 13th of December, he was placed on the committee for Irish affairs, was made lord lieutenant of Durham on the 10th of February 1642, became a member of the committee of both kingdoms on the 7th of February 1644, and in this capacity attended the Scots army in 1645, while the parliament in the treaty of Uxbridge demanded for him from Charles a barony and the repayment of his losses. He adhered to the parliament after the king's death, and in the first parliament of the Protectorate he was returned for Kent, but the House had refused to appoint him a member of the council of state in February 1650. He died in 1654. He had married Frances, daughter and co-heir of Thomas Darcy of Tolleshurst Darcy in Essex, by whom he had a large family of children, of whom the eldest son, Sir Henry Vane, the younger, is separately noticed.

Clarendon invariably speaks of Vane in terms of contempt and reproach. He describes him as merely fit for court duties, "of very ordinary parts by nature and . . . very illiterate. But being of a stirring and boisterous disposition, very industrious and very bold, he still wrought himself into some employment." He declares that motives of revenge upon Strafford influenced not only his conduct in the impeachment but his unsuccessful management of the king's business in the Short Parliament, when he "acted that part maliciously and to bring all into confusion." The latter accusation, considering the difficulties of the political situation and Vane's total want of ability in dealing with them, is probably unfounded. On the general charge of betraying the king's cause, Vane's mysterious conduct in the impeachment, his great intimacy with Hamilton, and the favour with which he was immediately received by the Opposition on his dismissal from office, raise suspicions not altogether allayed by the absence of proof to substantiate them, while the alacrity with which he transferred himself to the parliament points to a character, if not of systematic treachery, yet of unprincipled and unscrupulous time-serving. Materials, however, to elucidate the details and motives of his ill-omened career have hitherto been wanting.

VANE, SIR HENRY (1613–1662), English statesman and author, known as "the younger" to distinguish him from his father, Sir Henry Vane (*q.v.*), was baptized on the 26th of May 1613, at Debden, Essex. After an education at Westminster, where he was noted for his high and reckless spirits, and at Magdalen Hall, Oxford, where he neither matriculated nor took his degree, he was attached to the embassy at Vienna and at Leiden and Geneva. He had already acquired strong Puritan views which, in spite of the personal efforts of Laud, who made the attempt at the king's request, he refused to give up. In 1635, in order to obtain the free exercise of his religion, he emigrated to Massachusetts, where he was elected governor in 1636. After one year in office, during which he showed some administrative ability, he was defeated by Winthrop, the former governor, chiefly on account of the protection he had given to Mrs Hutchinson in the religious controversies which she raised. He, however, never lost his interest in the colonies, and used his influence hereafter on several occasions in their support.

Vane returned to England in August 1637. He was made joint-treasurer of the navy with Sir W. Russell in January 1639, was elected for Hull in the Short and Long Parliaments, and was knighted on the 23rd of June 1640. Accidentally finding among his father's papers some notes of Strafford's speech in the council of May 5, 1640, he allowed Pym to take a copy, and was thus instrumental in bringing about Strafford's downfall. He carried up the impeachment of Laud from the Commons, was a strong supporter, when on the committee of religion, of the "Root and Branch" bill, and in June 1641 put forward a scheme of church government by which commissioners, half lay and half cleric, were to assume ecclesiastical jurisdiction in each diocese. During the absence of Pym and Hampden from the House at the time of Charles's attempted arrest of the five members, Vane led the parliamentary party, and was finally dismissed from his office in December 1641, being reinstated by the parliament in August 1642. The same month he was placed upon the committee of defence. In 1643 he was the leading man among the commissioners sent to treat for a league with the Scots. Vane, who was bitterly opposed to the tyranny of the Presbyterian system, was successful in two important points. The aim of the Scots was chiefly the propagation of their discipline in England and Wales, and for this they wanted only a "covenant." The English desired a political "league." Vane succeeded in getting the bond termed the Solemn League and Covenant, and further in substituting the whole expression "*according to the word of God and* the example of the best Reformed churches" for the latter part alone. He succeeded to the leadership of the party on Pym's death. He promoted, and became a chief member of, the committee of both kingdoms established in February 1644, and was sent to York in the summer of the year to urge Fairfax and Manchester to march against Prince Rupert, and secretly to propose the king's deposition. In 1645 he was one of the negotiators of the treaty of Uxbridge. He was, with Cromwell, a prime mover in the Self-Denying Ordinance and the New Model, and his adherence to the army party and to religious tolerance now caused a definite breach with the Scots. Vane had at the Westminster Assembly, writes Baillie indignantly, "prolixly, earnestly and passionately reasoned for a full liberty of conscience to all religions," a policy directly opposed to Presbyterianism, and his leadership terminated when the latter party obtained the supremacy in parliament in 1646. During the subsequent struggle he was one of the six commissioners appointed to treat with the army by the parliament, and endeavoured to effect a compromise, but failed, being distrusted by both the Levellers and the Presbyterians. His views of government may be studied in *The People's Case Stated*, written shortly before his death. "The power which is directive, and states and ascertains the morality of the rule of obedience, is in the hand of God; but the original, from whence all just power arises, which is magistratical and coercitive, is from the will or free gift of the people, who may either keep the power in themselves or give up their subjection and will in the hand of another." King and people were bound by "the fundamental constitution or compact," which if the king violated, the people might return to their original right and freedom.

In spite, however, of these free opinions, Vane still desired the maintenance of the monarchy and the constitution. He voted for a declaration to this effect on the 28th of April 1648, and had consistently opposed the various votes of "non-addresses." Several communications had already been fruitlessly attempted with Vane from the king's side, through the agency of Lord Lovelace in January 1644, and through that of John Ashburnham in March 1646. Vane now supported the renewal of negotiations, and was appointed on the 1st of September 1648 one of the commissioners for the treaty of Newport. He here showed a desire to come to terms on the foundation of toleration and a "moderate episcopacy," of which Cromwell greatly disapproved, and opposed the shaking off of the conferences. He absented himself from parliament on the occasion of "Pride's Purge," and remained in retirement until after the king's death, a measure in which he took no part, though he continued to act as a member of the government. On the 14th of February 1649 he was placed on the council of state, though he refused to take the oath which expressed approbation of the king's execution. Vane now showed himself an able administrator. He served on innumerable committees of importance, and was assiduous in his attendance. He furnished the supplies for Cromwell's expedition to Scotland, and was one of the commissioners sent there subsequently to settle the government and negotiate a union between the two countries. He showed great energy in colonial and foreign affairs, was a leading member of the committee dealing with the latter, and in 1651 went on a secret mission to negotiate with Cardinal de Retz, who was much struck with his ability, while his knowledge of foreign policy, in which he inclined in favour of Holland, earned the praise also of Milton. To Vane, as chief commissioner of the navy, belongs largely the credit of the victories obtained against Van Tromp.

In domestic politics Vane continued to urge his views of toleration and his opposition to a state church. On the 9th of January 1650 he brought forward as chairman the report of a committee on the regulation of elections. He wished to reform the franchise on the property basis, to disfranchise some of the existing boroughs, and to give increased representation to the large towns; the sitting members, however, were to retain their seats. In this he was opposed to Cromwell, who desired an entirely new parliament and the supremacy of the army representation. On the 20th of April Cromwell forcibly dissolved the Long Parliament while in the act of passing Vane's bill. On the latter's protesting, "This is not honest; yea, it is against morality and common honesty," Cromwell fell a-railing at him, crying out with a loud voice, "O Sir Henry Vane, Sir Henry Vane; the Lord deliver me from Sir Henry Vane!" (Ludlow, *Mem.* i. 353). Hitherto they had lived on intimate terms of friendship, but this incident created a permanent breach. In his seclusion at Raby he now wrote the *Retired Man's Meditations* (1655). In 1656 he proposed in *A Healing Question* (reprinted in the "Somers Tracts," vol. vi. ed. Scott) a new form of government, insisting as before upon a Puritan parliament supreme over the army. The seditious movements of the Anabaptists were also attributed to his influence, and on the 29th of July 1656 he was summoned before the council. Refusing to give security not to disturb the public peace, he was on the 9th of September sent prisoner to Carisbrooke Castle, and there remained until the 31st of December. He addressed a letter to Cromwell in which he repudiated the extra-parliamentary authority he had assumed. In the parliament of Richard Cromwell he was elected for Whitchurch, when he urged that the protector's power should be strictly limited, and the negative voice of the new House of Lords disallowed.

Subsequently he allied himself with the officers in setting aside the protectorate and in restoring the Long Parliament, and on Richard Cromwell's abdication he regained his former supremacy in the national counsels. He was a member of the committee of safety and of the council of state appointed in May, was commissioner for the navy and for the appointment of army officers, managed foreign affairs and superintended finance. He adhered to Lambert, remained a member of the government after the latter had turned out the Long Parliament, and endeavoured to maintain it by reconciling the disputing generals and by negotiating with the navy, which first deserted the cause. In consequence, at the restoration of the Long Parliament he was expelled the House and ordered to retire to Raby.

At the Restoration Vane was imprisoned in the Tower by the king's order. After several conferences between the houses of parliament, it was agreed that he should be excepted from the indemnity bill, but that a petition should be sent to Charles asking that his life might be spared. The petition was granted. On the meeting, however, of the new parliament of 1661, a vote was passed demanding his trial on the capital charge, and Vane was taken back to the Tower in April 1662 from the Scilly Isles, where he had been imprisoned. On the 2nd of June he appeared before the king's bench to answer the charge of high treason, when he made a bold and skilful defence, asserting the sovereign power of parliament in justification of his conduct. He was, however, found guilty, and executed on Tower Hill on the 14th of June 1662. He had married, in 1640, Frances, daughter of Sir Christopher Wray of Barlings, by whom he had a large family of sons and daughters. Of these Christopher, the fifth son, succeeded to his father's estates and was created Baron Barnard by William III.

Vane's great talents as an administrator and statesman have been universally acknowledged. He possessed, says Clarendon, "extraordinary parts, a pleasant wit, a great understanding, a temper not to be moved," and in debate "a quick conception and a very sharp and weighty expression." His patriotism and assiduity in the public service, and complete freedom from corruption, were equally admirable and conspicuous. His religious writings, apart from his constant devotion to toleration and dislike of a state church, are exceedingly obscure both in style and matter, while his enthusiasm and fanaticism in speculative doctrine combine curiously, but not perhaps incongruously, with exceptional sagacity and shrewdness in practical affairs. "He had an unusual aspect," says Clarendon, "which . . . made men think there was something in him of the extraordinary; and his whole life made good that imagination." Besides the works already mentioned and several printed speeches, Vane wrote: *A Brief Answer to a certain Declaration* of John Winthrop (reprinted in the Hutchinson Papers, publ. by the Prince Society, 1865); *A Needful Corrective or Balance in Popular Government* . . . in answer to Harrington's *Oceana*; *Of Love of God and Union with God*; two treatises, viz. (1) *An Epistle General to the Mystical Body of Christ on Earth*, (2) *The Face of the Times: A Pilgrimage into the Land of Promise* . . . (1664). *The Trial of Sir Henry Vane, Knight* (1662), contains, besides his last speech and details relating to the trial, *The People's Case Stated* (reprinted in Forster's *Life of Vane*), *The Valley of Jehoshaphat*, and *Meditations concerning Man's Life*. *A Letter from a True and Lawful Member of Parliament to one of the Lords of His Highness's Council* (1656), attributed to Vane, was written by Clarendon; and *The Light Shining out of Darkness* was probably by Henry Stubbe; while *The Speech against Richard Cromwell* is the composition of some contemporary pamphleteer.

VANE (formerly spelt "fane," *i.e.* pennon, flag; cf. Ger. *Fahne*, Du. *vaan*, Fr. *girouette*, Ital. *banderuola*, Ger. *Wetterfahne*), the weathercock on a steeple. Vanes seem in early times to have been of various forms, as dragons, &c.; but in the Tudor period the favourite design was a beast or bird sitting on a slender pedestal and carrying an upright rod, on which a thin plate of metal is hung like a flag, ornamented in various ways.

VAN HORNE, SIR WILLIAM CORNELIUS (1843–), Canadian financier, was born in Will county, Illinois, U.S.A., on the 3rd of February 1843, of Dutch descent. He was educated in the common schools of the state, and in 1857 began work as office boy in a railway station. His ability and force brought him to the front, and he rose till in 1881 he was appointed general manager of the Canadian Pacific railway. For the successful completion of this great road his strong will and mental grasp were largely responsible, and he it was who not only controlled but steadily extended its operations during the lean years which followed. In 1884 he became vice-president of the line, in 1888 president, and in 1899 chairman of the board of directors. From 1885 onward he was more and more associated with every branch of Canadian mercantile and financial life, and as a publicist gave shrewd expression to his views on political and economic questions. After the Spanish-American War (1898) he became one of the chief promoters of railway and industrial enterprise in Cuba. In May 1894 he was knighted by Queen Victoria in acknowledgment of his distinguished public services. He was also known as a patron of art and literature and an amateur painter of no little merit.

VANILLA, a flavouring agent largely used in the manufacture of chocolate, in confectionery and in perfumery. It consists of the fermented and dried pods of several species of orchids belonging to the genus *Vanilla*.[1] The great bulk of the commercial article is the produce of *V. planifolia*, a native of south-eastern Mexico, but now largely cultivated in several tropical countries, especially in Bourbon, the Seychelles, Tahiti and Java. The plant has a long fleshy stem and attaches itself by its aerial rootlets to trees; the roots also penetrate the soil and derive a considerable portion of their nourishment from it. The leaves are alternate, oval-lanceolate and fleshy; the light greenish flowers form axillary spikes. The fruit is a pod

Vanilla Plant (*Vanilla planifolia*). A, shoot with flower, leaf and aerial rootlets; B, pod or fruit.

from 6 to 10 in. long, and when mature about half an inch in diameter. The wild plant yields a smaller and less aromatic fruit, distinguished in Mexico as *Baynilla cimarona*, the cultivated vanilla being known as *B. corriente*.

Vanilla was used by the Aztecs of Mexico as an ingredient in the manufacture of chocolate before the discovery of America by the Spaniards, who adopted its use. The earliest botanical notice is given in 1605 by Clusius (*Exoticorum Libri Decem*), who had received fruits from Hugh Morgan, apothecary to Queen Elizabeth; but he seems to have known nothing of its native country or uses. The Mexican vanilla had been introduced to cultivation before the publication of the second edition of Philip Miller's *Gardeners' Dictionary* (1739). It was reintroduced by the marquis of Blandford, and in 1807 a flowering specimen was figured and described by R. A. Salisbury (*Paradisus*, London, t. 82). Mexican vanilla is regarded as the best. It is principally consumed in the United States. In Bourbon about 3000 acres are under cultivation; the crop is sent to Bordeaux, the chief centre of the trade in France. Its odour is said to differ from the Mexican variety in having a suggestion of tonqua bean. The Seychelles produce large quantities of exceedingly fine quality; the produce of these islands goes chiefly to the London market. The Java vanilla, grown chiefly in Krawang and the Preanger Regencies, is shipped to Holland. The Tahiti produce is inferior in quality.

Mr Hermann Mayer Senior, in the *Chemist and Druggist*, June 30, 1906, gives the following figures, which approximately represent the world's output of vanilla during the seasons 1905–1906: Bourbon, 70 tons; Seychelles, 45 tons; Mauritius, 5 tons; Comores, Mayotte, Madagascar, &c., 120 tons; Guadeloupe, Java, Ceylon and Fiji, 10 tons; Mexica, 70 tons; Tahiti, 100 tons—total, about 420 tons.

The best varieties of vanilla pods are of a very dark chocolate brown or nearly black colour, and are covered with a crystalline efflorescence technically known as *givre*, the presence of which is taken as a criterion of quality. The peculiar fragrance of vanilla is due to vanillin, $C_8H_8O_3$, which forms this efflorescence. Chemically speaking, it is the aldehyde of methyl-protocatechuic acid. It is not naturally present in the fleshy exterior of the pod, but is secreted by hair-like papillae lining its three internal angles, and ultimately becomes diffused through the viscid oily liquid surrounding the seeds. The amount of vanillin varies according to the kind: Mexican vanilla yields 1·69, Bourbon or Réunion 1·9 to 2·48, and Java 2·75%. Besides vanillin, the pods contain vanillic acid (which is odourless), about 11% of fixed oil, 2·3% of soft resin, sugar, gum and oxalate of lime.

Vanillin forms crystalline needles, fusible at 81° C., and soluble in alcohol, ether and oils, hardly soluble in cold, but more so in boiling water. Like other aldehydes, it forms a compound with the alkaline bisulphites, and can by this means be extracted from bodies containing it. Vanillin has been found in Siam benzoin and in raw sugar, and has been prepared artificially from coniferin, a glucoside found in the sapwood of fir-trees, from asafoetida, and from a constituent of oil of cloves named eugenol. It is from the last-named that vanillin is now prepared on a commercial scale, chiefly in Germany. Vanillin does not appear to have any physiological action on human beings when taken in small doses, as much as 10 to 15 grains having been administered without noxious results. On small animals, however, such as frogs, it appears to act as a convulsive. It has been suggested as a stimulant of an excito-motor character in atonic dyspepsia. It is a constituent of Günzburg's reagent (phloro-vanillin-glucin) for the detection of free hydrochloric acid in the gastric contents. The poisonous effects

[1] Span. *vainilla*, dim. of *vaina*, a pod.

that have on several occasions followed from eating ices flavoured with vanilla are not to be attributed to the vanilla, but probably to the presence of *tyrotoxicon* (*Pharm. Journ.* [3], xvii. p. 150), a poison found in milk which has undergone certain putrefactive changes, and producing choleraic effects, or perhaps to the presence of microscopic fungi in the vanilla, the plantations being liable to the attack of *Bacterium putredinis.* Workmen handling the beans in the Bordeaux factories are subject to itching of the hands and face; but this is caused by an *Acarus* which occupies the end of the pod. In some cases, however, symptoms of dizziness, weariness and malaise, with muscular pains, have been felt, due possibly to the absorption of the oily juice by the hands of the workmen.

See also R. A. Rolfe, "Vanillas of Commerce," in *Kew Bulletin* (1895), p. 169, and "Revision of the Genus Vanilla," in *Journal of The Linnean Society* (Botany), xxxii. 439 (1896); also S. J. Galbraith, on "Cultivation in the Seychelles," *U.S. Dept. of Agriculture, Division of Botany, Bulletin 21* (1898).

VANINI, LUCILIO, or, as he styled himself in his works, Giulio Cesare (1585–1619), Italian free-thinker, was born at Taurisano, near Naples, in 1585. He studied philosophy and theology at Rome, and after his return to Naples applied himself to the physical studies which had come into vogue with the Renaissance. Like Giordano Bruno, though morally and intellectually inferior to him, he was among those who led the attack on the old scholasticism and helped to lay the foundation of modern philosophy. Vanini resembles Bruno, not only in his wandering life and in his tragic death, but also in his anti-Christian bias. From Naples he went to Padua, where he came under the influence of the Alexandrist Pomponazzi (*q.v.*), whom he styles his divine master. At Padua he studied law, and was ordained priest. Subsequently he led a roving life in France, Switzerland and the Low Countries, supporting himself by giving lessons and disseminating anti-religious views. He was obliged to flee from Lyons to England in 1614, but was imprisoned in London for some reason for forty-nine days. Returning to Italy he made an attempt to teach in Genoa, but was driven once more to France, where he made a valiant effort to clear himself of suspicion by publishing a book against atheists, *Amphitheatrum Aeternae Providentiae Divino-Magicum* (1615). Though the definitions of God are somewhat pantheistic, the book is sufficiently orthodox, but the arguments are largely ironical, and cannot be taken as expounding his real views. Vanini expressly tells us so in his second (and only other published) work, *De Admirandis Naturae Reginae Deaeque Mortalium Arcanis* (Paris, 1616), which, originally certified by two doctors of the Sorbonne, was afterwards re-examined and condemned to the flames. Vanini then left Paris, where he had been staying as chaplain to the maréchal de Bassompierre, and began to teach in Toulouse. In November 1618 he was arrested, and after a prolonged trial was condemned, as an atheist, to have his tongue cut out, and to be strangled at the stake, his body to be afterwards burned to ashes. The sentence was executed on the 9th of February 1619.

Vanini* (Strassburg, 1869); Cesare Cantu, *Gli Eretici d'Italia* (Turin, 1867), iii. 72 ff.; Fuhrmann, *Leben und Schicksale* (Leipzig, 1800); Vaïsse, *L. Vanini* (Paris, 1871); Palumbo, *Vanini, e i suoi tempi* (Naples, 1878); Passamonti in *Rivista italiana di filosofia* (1893), vol. iii.

VANLOO, CHARLES ANDREW (1705–1765), subject painter, a younger brother of John Baptist Vanloo (*q.v.*), was born at Nice on the 15th of February 1705. He received some instruction from his brother, and like him studied in Rome under Luti. Leaving Italy in 1723, he worked in Paris, where he gained the first prize for historical painting. After again visiting Italy in 1727, he was employed by the king of Sardinia, for whom he painted a series of subjects illustrative of Tasso. In 1734 he settled in Paris, and in 1735 became a member of the French Academy; and he was decorated with the order of St Michael and appointed principal painter to the king. By his simplicity of style and correctness of design, the result of his study of the great Italian masters, he did much to purify the modern French school; but the contemporary praise that was lavished upon his productions now appears undue and excessive. His "Marriage of the Virgin" is preserved in the Louvre. He died at Paris on the 15th of July 1765.

VANLOO, JOHN BAPTIST (1684–1745), French subject and portrait painter, was born at Aix in Provence on the 14th of January 1684. He was instructed in art by his father. Having at an early age executed several pictures for the decoration of the church and public buildings at Aix, he was employed on similar work at Toulon, which he was obliged to leave during the siege of 1707. He was patronized by the prince of Carignan, who sent him to Rome, where he studied under Benedetto Luti. Here he was much employed on church pictures, and in particular executed a greatly praised "Scourging of Christ" for St Maria in Monticelli. At Turin he painted the duke of Savoy and several members of his court. Then, removing to Paris, where he was elected a member of the French Academy, he executed various altar-pieces and restored the works of Primaticcio at Fontainebleau. In 1737 he went to England, where he attracted attention by his portrait of Colley Cibber and of Owen McSwiny, the theatrical manager; the latter, like many other of Vanloo's works, was engraved in mezzotint by the younger Faber. He also painted Sir Robert Walpole, whose portrait by Vanloo in his robes as chancellor of the exchequer is in the National Portrait Gallery (London), and the prince and princess of Wales. He did not, however, practise long in England, for his health failing he retired to Paris in 1742, and afterwards to Aix, where he died on the 19th of December 1745. His likenesses were striking and faithful, but seldom flattering, and his heads are forcible in colouring. The draperies and accessories in his pictures were usually painted by Van Achen, Eccardt and Root.

VANNES, a town of western France, capital of the department of Morbihan, 84 m. N.W. of Nantes on the railway to Brest. Pop. (1906), town, 16,728; commune, 23,561. It is situated 10 m. from the open sea, at the confluence of two streams forming the Vannes river, which debouches into the land-locked Gulf of Morbihan about a mile below the town. The narrow, steep and crooked streets of the old town, which lie on a hill facing the south, are surrounded by fortifications of the 14th, 15th and 17th centuries, pierced by four gates and flanked by nine towers and five bastions, connected by battlements. In the Constable's Tower Olivier de Clisson was confined in 1387. The modern suburbs, with the port, the public buildings, barracks, convents, squares and promenades, notably the Garenne and the park of the Prefecture, surround the old town. The archaeological museum, the contents of which are mainly the fruit of excavations at Carnac and elsewhere in the vicinity, includes one of the richest collections of prehistoric remains in Europe. There are also a museum of natural history and a library. The cathedral of St Peter overlooks the old town; burnt by the Normans in the 10th century, it was rebuilt in the 13th, 15th and 18th centuries. It has remains of a cloister and contains the relics and tomb of the Spanish Dominican preacher St Vincent Ferrier, who died at Vannes in 1419. The curious round Chapelle du Pardon to the left of the nave was built in 1537 in the Italian style. Some interesting old houses, including that of the presidents of the parlement of Brittany, the rich private collections of M. de Limur, and the church of St Paterne (18th century) are also worthy of mention. There is a monument to Le Sage, born near Vannes. Vannes is the seat of a prefect, a bishop and a court of assizes, and has tribunals of first instance and of commerce and a branch of the Bank of France. A communal college is among the educational institutions. Among the industries are building, tanning and cotton-weaving. The port of Vannes, to the south of the town, is formed by the Vannes river and is accessible only to small vessels. Vessels of 800 tons can make the harbour of Conleau about 2½ m. from the town.

Vannes (*Dariorigum*), the capital of the Veneti (whence *Gwened*, the Breton name of the town), was at the head of the Armorican league against Julius Caesar, who in 56 B.C. overcame their fleet and opened up their country by six roads. St Paternus, the first bishop, was consecrated in 465. In the 5th century Vannes was ruled for a time by independent counts, but soon came under the yoke of the Franks. Nomenoé, the lieutenant of Louis I., the Pious, in Brittany, assumed the title of king in 843, and one of his brothers was the founder of a line of counts who distinguished themselves against the Normans in the 9th and 10th centuries. Vannes became part of the duchy of Brittany at the end of the 10th century. The estates of Brittany met there for the first time in 1203 to urge Philip Augustus to avenge the death of Arthur of Brittany. In the course of the War of Succession the town was besieged four times in 1342. Duke John IV. built here the castle of L'Hermine and made it his habitual residence. In 1487 the town was for a year in the hands of Charles VIII. of France. In 1532 Brittany was definitively united to France. The estates met at Vannes several times in the 17th and 18th centuries. During the Revolution this town was the scene of the execution in 1795 of some of the prisoners after the royalist disaster at Quiberon.

VAN RENSSELAER, STEPHEN (1764–1839), American political leader and soldier, "last of the patroons," was born at New York City on the 1st of November 1764. He was fifth in descent from KILLIAN VAN RENSSELAER (*c.* 1580-1645), the original patroon of Rensselaerwyck, New York, who acquired his large estates between 1630 and 1637. Stephen was graduated at Harvard in 1782. In 1789–90 he was a member of the New York Assembly, and from 1791 to 1795 served as a member of the state Senate. He was lieutenant-governor of New York (1795–1801) for the two terms in which John Jay was governor. In 1801 he presided over the state constitutional convention, and from 1808 to 1810 was again in the Assembly. He was an ardent promoter of the Erie Canal, and as a commissioner to examine the proposed route, &c., he reported favourably to the Assembly in 1811. In the second war with Great Britain he commanded the First Division of the detached militia of the state of New York, with the rank of major-general, and on the 13th of October 1812 was defeated at the battle of Queenston Heights. As he was a Federalist he was severely criticised and censured for this defeat and resigned from the army. At the close of the war the Erie Canal project was renewed, and from 1816 till his death he was a member of the board of canal commissioners, and for nearly fifteen years was its president. In 1818 he was again elected to the Assembly; in 1819 he became a regent of the State University of which he was for a time chancellor; and in 1821 he was a delegate to the New York constitutional convention. From 1822 to 1829 he was a member of the National House of Representatives,[1] and there voted for John Quincy Adams for the presidency, and served as chairman of the committee on agriculture. In 1820–23 he sent out at his own expense Professors Amos Eaton (1776–1842) and Edward Hitchcock to make extensive surveys, results of which were published as *An Agricultural and Geological Survey of the District adjoining the Erie Canal* (Albany, 1824). In 1824 he founded a school in Troy which was incorporated two years later as the Rensselaer Polytechnic Institute. He died at Albany, New York, on the 26th of January 1839.

See D. D. Barnard, *A Discourse on the Life, Services and Character of Stephen Van Rensselaer* (Albany, 1839).

VANSITTART, HENRY (1732–1770 or 1771), Anglo-Indian governor, was born in London on the 3rd of June 1732. His father, Arthur van Sittart (1691–1760), and his grandfather, Peter van Sittart (1651–1705), were both wealthy merchants and directors of the Russia company. Peter, a merchant adventurer, who had migrated from Danzig to London about 1670, was also a director of the East India company. The family name is taken from the town of Sittard in Limburg. Educated at Reading school and at Winchester college, Henry Vansittart joined the society of the Franciscans, or the "Hell-fire club," at Medmenham, his elder brothers, Arthur and Robert, being also members of this fraternity. In 1745 he entered the service of the East India company and sailed for Fort St David; here he showed himself very industrious, made the acquaintance of Robert Clive and rose rapidly from one position to another. As a member of the council of Madras he helped to defend the city against the French in 1759, and in July 1760 he went to Bengal as president of the council and governor of Fort William. Courageously facing the difficulties of his new position, which included a serious lack of funds, he deposed the subadar of Bengal, Mir Jafar, whom he replaced by his son-in-law, Mir Kasim, a circumstance which increased the influence of England in the province. He was, however, less successful in another direction. Practically all the company's servants were traders in their private capacity, and as they claimed various privileges and exemptions this system was detrimental to the interests of the native princes and gave rise to an enormous amount of corruption. Vansittart sought to check this, and in 1762 he made a treaty with Mir Kasim, but the majority of his council were against him and in the following year this was repudiated. Reprisals on the part of the subadar were followed by war, and, annoyed at the failure of his pacific schemes, the governor resigned and returned to England in 1764. His conduct was attacked before the board of directors in London, but events seemed to prove that he was in the right, and in 1769 he became a director of the company, having in the previous year obtained a seat in parliament. He was now sent on an important mission to India; he left England in September 1769, but the ship in which he sailed was lost at sea late in 1770 or early in 1771. One of his five sons was Nicholas Vansittart, Baron Bexley (*q.v.*). To defend his conduct in Bengal Vansittart published some papers as *A Narrative of the Transactions in Bengal from 1760 to 1764* (London, 1766).

Vansittart's brother, Robert Vansittart (1728–1789), who was educated at Winchester and at Trinity College, Oxford, was regius professor of civil law at Oxford from 1757 until his death on the 31st of January 1789. Another brother, George Vansittart (1745–1825), of Bisham Abbey, Berkshire, was the father of General George Henry Vansittart (1768–1824) and of Vice-Admiral Henry Vansittart (1777–1843).

VAN'T HOFF, JACOBUS HENDRICUS (1852–), Dutch chemist and physicist, was born in Rotterdam on the 30th of August 1852. He studied from 1869 to 1871 at the polytechnic at Delft, in 1871 at the university of Leiden, in 1872 with F. A. Kekulé at Bonn, in 1873 with C. A. Wurtz at Paris, and in 1874, when he took his doctor's degree, with E. Mulder at Utrecht. In 1876 he became lecturer on physics at the veterinary school at Utrecht, and two years later he was chosen professor of chemistry, mineralogy and geology in Amsterdam University. In 1894 he declined an invitation to the chair of physics at Berlin University, but in 1896 he went to Berlin as professor to the Prussian Academy of Sciences, with a salary and a laboratory, but freedom to do whatever he liked; and at the same time he accepted an honorary professorship in the university so that he might lecture if he were so minded. On taking up these appointments he announced that, the application of mathematics to chemistry remaining his chief aim, he proposed to devote himself to the study of the formation of oceanic salt deposits, with special reference to the Stassfurt deposits. He may be regarded as the founder of the doctrine of stereoisomerism (*q.v.*), for he was the first, in 1874, to introduce a definite mechanical theory of valency, and to connect the optical activity exhibited by many carbon compounds with their chemical constitution. In respect of this doctrine of the "asymmetric carbon atom," van't Hoff's name is generally linked with that of J. A. le Bel (born on the 21st of January 1847, at Pechelbronn, Lower Alsace), who, only two months later, independently enunciated the theory of asymmetric combinations with carbon; though it must be noted that J. Wislicenus, to whom van't Hoff, in fact, acknowledged his indebtedness, had already suggested that in order to explain the constitution of certain organic bodies, the tridimensional arrangement of atoms in space must be taken into account. For this work van't Hoff and Le Bel received the Davy medal

[1] He succeeded his cousin, Solomon Van Rensselaer (1744–1852), who was in the regular army in 1792–1800, who had fought under General Anthony Wayne at Maumee Rapids in 1794 and under Stephen Van Rensselaer at Queenston Heights in 1812, and who was in the House of Representatives in 1819–1822.

jointly from the Royal Society in 1893. From 1874 to 1884 van't Hoff's attention was mainly given to the law of mass-action, and he established the theorem known by his name, which connects quantitative displacement of equilibrium with change of temperature. From 1885 to 1895 he was engaged on the theory of solutions, and developing the analogy between dilute solutions and gases he showed that the osmotic pressure of a solution has the same value as the pressure that solute would exert if it were contained as a gas in the same volume as is occupied by the solution. From 1885 he published the *Zeitschrift für physikalische Chemie*, in collaboration with Professor W. Ostwald of Leipzig.

VAN WERT, a city and the county-seat of Van Wert county, Ohio, U.S.A., about 28 m. W. by N. of Lima. Pop. (1890) 5512; (1900) 6422 (221 foreign-born); (1910) 7157. Van Wert is served by the Pennsylvania and the Cincinnati Northern railways, and by an interurban electric line. Among the principal buildings are the city hall, the court house, the Brumback Library of Van Wert county (containing 14,650 volumes in 1908), the Home Office Building of the Home Guards of America (a fraternal society incorporated in 1899 and having about 16,000 members in 1910), and the Home Office Building of the Central Manufactures' Insurance Co. Van Wert is situated in a rich agricultural region. It has railway and machine shops and various manufactures. The municipality owns and operates the waterworks. Van Wert was settled about 1840, was incorporated as a town in 1848 and was chartered as a city in 1903. The county and the city were named in honour of Isaac Van Wert (1760–1828), one of the captors of Major John André.

VAPEREAU, LOUIS GUSTAVE (1819–1906), French man of letters and lexicographer, was born at Orleans on the 4th of April 1819. Educated at the École Normale he became a teacher of philosophy, and was entrusted by Victor Cousin with the preparation of his studies on the *Pensées* of Pascal. Under the empire his republican principles cost him his position, and Vapereau studied for the bar. He practised, however, little or not at all, and after 1870 he was appointed prefect of Cantal (1870) and of Tarn et Garonne (1871–73). From 1877 to 1888 he was inspector-general of public instruction. He was the author of some excellent editions of the classics, and of works on political and social questions, but he is famous for his valuable *Dictionnaire universel des contemporains* (1858; 6th ed., 1893), brought up to date in 1895 by a supplementary volume. He also drew up a *Dictionnaire universel des littérateurs* (1876). At the time of his death at Norsang-sur-Orge in 1906, he had been for twenty-six years a regular contributor to *L'Illustration*, some of his notes written for this journal being collected in 1896 as *L'Homme et la vie*.

VAPHIO, an ancient site in Laconia, Greece, on the right bank of the Eurotas, some 5 m. S. of Sparta. It is famous for its "bee-hive" tomb, excavated in 1889 by Dr Tsountas. This consists of a walled approach, or δρόμος, about 97 ft. long, leading to a vaulted chamber some 33 ft. in diameter, in the floor of which the actual grave was cut. The objects found here and transferred to the National Museum in Athens include a large number of gems and amethyst beads, together with articles in gold, silver, bronze, iron, lead, amber and crystal. But by far the finest of them are two golden cups decorated with scenes in relief, picturing the capture of bulls. These form perhaps the most perfect works of "Mycenaean" or "Minoan" art which have survived. It seems likely that the Vaphio cups do not represent a local art but were imported from Crete, which at that early period was far ahead of mainland Greece in artistic development. The tomb, which probably belonged to Amyclae rather than to Pharis, as is commonly stated, is now almost entirely destroyed.

See C. Tsountas, Ἐφημερὶς Ἀρχαιολογική (1889), 136–172; J. G. Frazer, *Pausanias's Description of Greece*, iii. 135 f. (with full bibliography); W. Ridgeway, *The Early Age of Greece*, i. 26–28; R. C. Bosanquet, *Journal of Hellenic Studies* (1904), xxiv. 317 ff.; A. Riegl, *Jahreshefte d. österr. arch. Institutes* (1906), ix. 1 ff. (M. N. T.)

VAPORIZATION. 1. In common language a *vapour* is a gaseous or elastic fluid, which emanates or evaporates from the surface of a solid or liquid at temperatures below its boiling-point. A *volatile* liquid or solid is one which evaporates rapidly at ordinary temperatures. It is a matter of common experience that evaporation is accelerated by currents of air, or by the use of an exhaust pump, or by any process which removes the vapour rapidly from the liquid. On the other hand, it is retarded, and finally ceases, if the vapour is allowed to accumulate in a closed space. When this equilibrium state is reached, the space is said to be *saturated* with the vapour; the density of the vapour is then the maximum which can exist in the presence of the liquid at the temperature of the experiment, and its pressure is called the *saturation-pressure*. The term vapour-pressure, when used without qualification, is also generally employed to denote the saturation or maximum pressure. Dalton showed that the saturation-pressure of a vapour depends only on the temperature, and is unaffected by the presence of any neutral gas or vapour. This relation has been more accurately verified by many subsequent observers, and the exceptions to it have been minutely studied and elucidated. The saturation-pressure invariably increases rapidly with rise of temperature, according to a regular law which has been the subject of many elaborate investigations. When the vapour-pressure of a liquid becomes equal to the external pressure, bubbles of vapour are freely formed in the interior of the liquid by the familiar process of boiling or ebullition. The temperature at which this occurs under the normal atmospheric pressure of 760 mm. of mercury (reduced to 0° C. and sea-level in latitude 45°) is termed the *boiling-point* (B.P.) of the liquid, and is usually determined by taking the temperature of the saturated vapour under normal pressure, to avoid error from superheating (see below, 3) of the liquid. If the external pressure remains constant, the temperature will also remain constant, provided that the liquid is pure and that its composition remains unaltered, until the whole is vaporized. If, on the other hand, the liquid is contained in a *closed* space, it may be made to boil at much lower temperatures by diminishing the pressure; or the temperature of the liquid may be raised considerably above the normal boiling-point, as in the boiler of a steam-engine, if the pressure is raised by preventing the free escape of the vapour. In all cases, if the temperature is given, there is a corresponding equilibrium or saturation-pressure of the vapour, and vice versa, in accordance with Dalton's law. It was shown, however, by Cagniard de la Tour (*Ann. Chim. Phys.*, 1822, 1823) that the temperature and pressure of the liquid could not be raised indefinitely in this manner. By heating liquids in strong glass bulbs with manometers attached, he found that at a certain temperature the meniscus or curved surface separating the liquid from the vapour disappeared, and the bulb became filled with an apparently uniform substance. The temperature at which this mixing of liquid and vapour occurs is definite for each liquid, and is called the *critical temperature*. La Tour found the critical temperature in the case of water to be 362° C., a result which has been remarkably confirmed by later researches (Cailletet, *Ann. Chim. Phys.* 25, p. 519, 1892). In many books of recent years it has been the custom, following a suggestion of Andrews, to restrict the term "gas" to temperatures above the critical temperature, and the term "vapour" to temperatures below. But this is often inconvenient in practice, as there is no sudden change in the gaseous phase at ordinary pressures on passing the critical temperature. It is more convenient to employ the terms "vapour" only when discussing the properties of the gaseous phase in relation to the liquid or solid, and to follow the common usage in describing substances like CO_2, or even SO_2 and NH_3, as gases at ordinary temperatures and pressures.

2. *Continuity of State.*—The form of the isothermal curve, representing the compression of a vapour at constant temperature, consists, as shown in fig. 1, A, of three discontinuous branches. The relation between pressure and volume for an

unsaturated vapour is represented by the branch DE, which is similar to the isothermal of a gas obeying Boyle's law. When the saturation-pressure is reached at D the vapour begins to condense, and the volume diminishes without further increase of pressure, giving the isopiestic branch DCB. At B, when the vapour is completely liquefied, further compression produces a rapid rise of pressure, as shown by the branch BA, representing

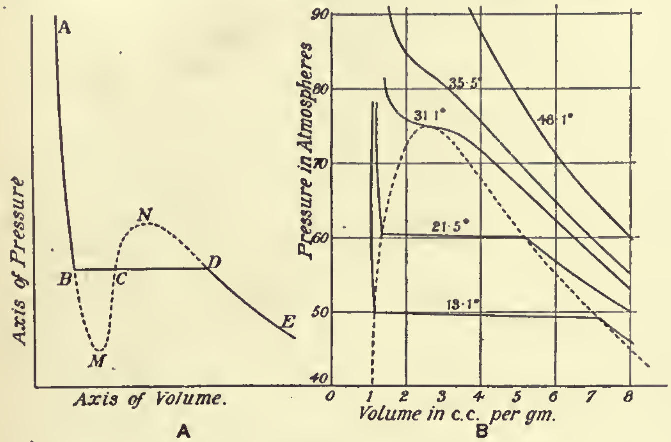

FIG. 1.

A, James Thomson Isothermal; B, Isothermals of CO_2 (Andrews).

the behaviour of the liquid. It is possible, however, to trace the branch DN for the supersaturated vapour continuously beyond D without liquefaction in the absence of nuclei. It is similarly possible to trace the liquid branch ABM beyond B to lower pressures in the absence of dissolved gases. As the temperature is raised, the length of the branch BD, representing the increase of volume in passing from the liquid to the gas, diminishes, as shown in fig. 1, B, which represents the isothermals of CO_2,[1] according to Andrews (*Phil. Trans.* 1869). Above the critical temperature, the discontinuities at B and D disappear from the isothermal curve, and it is impossible to obtain separation of the two states, liquid and gas, however great the pressure applied. The critical pressure is the vapour-pressure of the liquid at the critical temperature. It is possible to obtain a perfectly continuous passage from the gaseous to the liquid state by keeping the vapour at a pressure greater than the critical pressure while it is cooled from a temperature above the critical point, at which it would expand indefinitely (if the pressure were reduced) without separation into two phases, to a temperature below the critical point, at which expansion would produce separation into liquid and vapour as soon as the pressure was reduced to the saturation value. It was maintained by Andrews, on the basis of these and similar observations, that the gaseous and liquid states were merely widely separated forms of the same condition of matter, since one could be converted into the other without any breach of continuity or sudden evolution of heat or change of volume; just as an amorphous solid in the process of fusion becomes gradually more and more plastic as the temperature is raised, and passes into the state of a viscous liquid with continually diminishing viscosity. The same idea was further developed by James Thomson (*Proc. R.S.*, 1871), who suggested that the discontinuity of the isothermal at temperatures below the critical point was only apparent. He supposed that the extensions of the liquid and vapour curves BM, DN, in fig. 1, A, representing the states of superheated liquid and supersaturated vapour, might theoretically be joined by a continuous curve MN, representing a homogeneous transformation, which, however, could not be realized in practice, as the state of the substance corresponding to this part of the curve would be unstable. Maxwell (*Nature*, 1875) showed that the straight line BCD representing the saturation-pressure must cut off loops BMC, CND, of equal area from this imaginary isothermal; otherwise it would be theoretically possible to obtain a balance of work without any difference of temperature by taking the substance through the isothermal cycle BCDNCMB. The theoretical isothermal of James Thomson is qualitatively represented by an equation of the type devised by Van der Waals, in which the mutual attraction of the molecules of a gas is regarded as equivalent to an internal pressure of the form a/v^2, which he supposes identical with the capillary pressure of the liquid. It has been found, however, that this simple expression is not sufficiently exact. It is probable that it is not merely a question of varying attraction between similar molecules. A vapour should rather be regarded as containing a certain proportion of compound or coaggregated molecules, which partially dissociate when the pressure is diminished or the temperature raised. A liquid similarly contains dissolved molecules of vapour, and the state of equilibrium is more nearly analogous to that between conjugate saturated solutions (*e.g.* water and phenol).

[1] The slight increase of pressure observed during condensation was attributed by Andrews to the presence of a trace of air in the CO_2.

3. *Effect of Capillary Pressure on Ebullition.*—It was remarked at a very early date that water and other liquids could be raised under atmospheric pressure several degrees above their normal boiling-points in a clean glass vessel without ebullition occurring, and that, when a bubble was formed, it would expand explosively, producing the phenomenon of "bumping"; but that, if metallic filings or other bodies capable of supplying small bubbles of air were introduced, ebullition would proceed quietly at the normal temperature. L. Dufour succeeded in raising small drops of water, suspended in an oil mixture of suitable density, to a temperature of nearly 180° C. under atmospheric pressure. Similar observations lead to the conclusion that the phenomenon of ebullition, or boiling with the formation of bubbles, depends essentially on the presence of air or dissolved gas to provide nuclei for the starting-points of the bubbles. This is a natural consequence of the capillary pressure due to surface tension. The vapour-pressure p inside a small spherical bubble of radius r must exceed the pressure P in the liquid just outside the bubble by $2T/r$, where T is the surface tension of the liquid. The capillary pressure $2T/r$ may be very large if r is small. It is often stated on the strength of this relation that a bubble of radius r in a liquid will not expand indefinitely and rise to the surface as in ebullition, until the vapour-pressure p inside the bubble exceeds the external pressure P by $2T/r$. But this neglects the effect of the air or gas contained in the bubble, which plays an essential part in the phenomenon. A bubble of vapour containing no air or gas could not exist at all in stable equilibrium in a liquid. If its radius r were such as to make $2T/r$ greater than $p-P$, it would collapse entirely. A bubble containing gas, on the contrary, is in stable equilibrium when its radius r is such that the pressure of the gas and vapour inside it balance the external pressure P together with the capillary pressure $2T/r$. Any diminution of r produces an increase in the pressure of the gas which is more than sufficient to balance the increase of the capillary pressure $2T/r$. Supposing that the external pressure and temperature remain constant, the partial pressure of the gas inside the bubble varies inversely as the volume of the bubble, and may be represented by a/r^3. The size of the bubble is determined by the equation $p+a/r^3=P+2T/r$. The equilibrium is always stable if p is less than P. If p is greater than P, the equilibrium becomes unstable (and the bubble expands indefinitely), when the gas-pressure a/r^3 is one-third of the capillary pressure $2T/r$. This follows immediately by differentiating the above equation with respect to r, assuming the difference $p-P$ to remain constant. Substituting $2T/3r$ for a/r^3 we obtain the condition of stability,

$$p-P<4T/3r. \qquad (1)$$

In other words, the temperature of a liquid containing bubbles of radius r will rise until the excess pressure given by (1) is reached, and ebullition will begin as soon as the excess pressure amounts to two-thirds of the capillary pressure, and will not be delayed until the full capillary pressure is reached, as might appear at first sight. Bubbles 1 millimetre in diameter in water at P=760 mm. become unstable when the temperature reaches 100·05° C. approximately. To obtain a superheat of 10° C., where the excess pressure is 316 mm., the bubbles must not exceed about $\frac{1}{250}$th mm. diameter. The condensation of a vapour is also retarded by the effect of capillary pressure, but the relation in this case is somewhat different.

4. *Effect of Capillary Pressure on Vapour-Pressure.*—It was observed by Sir W. Thomson (Lord Kelvin) (*Phil. Mag.* iv. 42, p. 448, 1871) that if a capillary tube of radius r is immersed in a liquid of surface tension T, and the liquid rises to a height h above the plane surface (the whole being enclosed in a vessel of uniform temperature containing only the vapour of the liquid) the pressure of the vapour at the curved surface of the meniscus in the capillary tube will be less than that at the plane surface by the amount, gh/v, where g is the acceleration of gravity, and $1/v$ is the density of the vapour. But the vapour must be in equilibrium with the liquid at both surfaces. Otherwise perpetual motion would ensue

in an enclosure at uniform temperature. Consequently the equilibrium value of the vapour-pressure must vary with the curvature of the surface, or with the capillary pressure due to the curvature.

If P, p are the hydrostatic pressures in the liquid and vapour close to the meniscus, the difference $P-p=2T/r$. This is negative if r is negative, *i.e.* if the liquid rises in the tube, but is positive if the meniscus is convex and the liquid is depressed in the tube. If P_0, p_0 are the pressures in the liquid and vapour at the plane surface, $P_0=p_0$, and if $1/V$ is the density of the liquid, the differences of pressure in the liquid and vapour respectively corresponding to a difference of level h, are $P-P_0=-gh/V$, $p-p_0=-gh/v$. Combining these with the relation $P-p=2T/r$ and eliminating gh, we obtain, for the change of vapour-pressure $p-p_0$, due to change of pressure $P-p_0$, or to curvature $1/r$,

$$p-p_0=(P-P_0)V/v=2TV/r(v-V). \quad . \quad . \quad . \quad (2)$$

This increase of vapour-pressure with curvature affords a natural explanation of the fact that it is possible to cool a vapour considerably below the saturation temperature without condensation. The vapour-pressure in a fog containing small drops of radius r must exceed the normal vapour-pressure over a plane surface at the same temperature by the amount $2TV/r(v-V)$, which may be considerable if r is small. The same expression measures the supersaturation required to induce condensation in the presence of dust or other nuclei of radius r, and explains why it is that condensation always takes place on dust particles if any are present. This phenomenon forms the basis of J. Aitken's method of counting dust particles, or Wilson's method of counting electrical ions, which are also capable of acting as nuclei for starting condensation.

5. *Extension to Higher Pressures.*—The approximate formula above given for the effect of hydrostatic pressure on the vapour-pressure assumes the densities of the liquid and vapour constant, and is true for small differences of pressure only. If we take P_0 and p_0 to represent corresponding values of the pressure in the liquid and vapour at the same level (and not necessarily at the plane surface where $P_0=p_0$), and if the difference of level from P, p is small, substituting dP and dp for the small differences of pressure, we have accurately the relation $vdp=VdP$, where V and v are the specific volumes of the liquid and vapour under the pressures P and p respectively. In order to apply the formula to large differences of pressure, it is only necessary to integrate it at constant temperature between the required limits of P and p. We thus obtain the general equation,

$$\int_{p_0}^{p} v\,dp=\int_{P_0}^{P} V\,dP. \quad . \quad . \quad . \quad . \quad (3)$$

In applying the general equation (3) to an actual case, the compressibility of the liquid is the most uncertain factor. Assuming the compressibility constant, we may write $V=V_0(1-aP)$. For the vapour we may employ equation (17) THERMODYNAMICS, viz. $v=R\theta/p-c+b$, as a very close approximation over a wide range. The small quantities c and b are functions of the temperature only. Making these substitutions and integrating the equation we obtain

$$R\theta \log_e(p/p_0)=(c-b)(p-p_0)+V_0(P-P_0)-\tfrac{1}{2}aV_0(P^2-P^2_0). \quad (4)$$

C. T. R. Wilson (*Phil. Trans.* 1898) has observed that in the absence of nuclei a very fine mist is formed in a vapour on sudden expansion when its density is about eight times the saturation value. Putting $p/p_0=8$ in equation (4), and taking for water vapour $R=4{\cdot}61\times 10^6$, and $\theta=300°$ Abs. we find $P-P_0$ equal to 3000 atmospheres approximately as the pressure required to produce this degree of supersaturation, allowing for compressibility of V. The term $(c-b)$ may be neglected in this case, as p is small, but it would amount to about 17 % of PV at 200° C. The result obtained from the approximate formula (2) would be 9200 atmospheres, which is more than treble, and indicates the inapplicability of the simple formula in an extreme case. Taking $P=3000$ atmospheres, and assuming that the formula $2T/r$ applies for the capillary pressure, we find the equivalent radius of a nucleus corresponding to the fine misty condensation to be $5{\cdot}0\times 10^{-8}$ cm. This is a quantity of molecular dimensions, and lends support to the view that a vapour contains a certain proportion of coaggregated molecules, represented by the term c in the equation, which are capable of acting as nuclei for condensation. The analogous phenomenon of cloudy crystallization, which takes place in a supercooled liquid in the labile state, suggests that a liquid may similarly contain molecular crystals of solid, which would account, in the case of water, for its anomalous expansion and for the variation of its specific heat near the freezing-point.

For small values of the vapour-pressure p, the term $(c-b)$ $(p-p_0)$ in equation (4) may generally be neglected, as in the case of water at ordinary temperatures. For moderate values of P, not exceeding say 100 atmospheres, V may be taken as nearly constant, and the equation reduces to the simpler form $PV/R\theta=\log_e(p/p_0)$, which is often sufficiently exact.

6. *Application to a Solid.*—If we imagine a vertical column of solid in a porous vessel at uniform temperature surrounded by vapour, it would appear probable by similar reasoning that it would be in equilibrium under its own hydrostatic pressure with the pressure of the vapour at different levels. This would give the same formula as (2) for the variation of vapour-pressure, with V′, the specific volume of the solid, in place of V. But since the surface tension analogy does not exactly apply in the case of a solid, it is perhaps better to deduce the formula from a consideration of the effect of pressure on the freezing-point. The freezing-point θ_0 is the point at which the solid and liquid have the same vapour-pressure p_0. Otherwise they could not remain together in equilibrium. When the freezing-point is changed by pressure, the vapour-pressures p', p'', of the solid and liquid must be the same at the new freezing-point. The rise of the freezing-point $\theta-\theta_0$, for an increase of pressure $P-P_0$, is given by the thermodynamic equation (THERMODYNAMICS, equation (5))

$$L(\theta-\theta_0)/\theta_0=(P-P_0)(V''-V'), \quad . \quad . \quad . \quad (5)$$

where L is the latent heat of fusion, and V′, V″ are the specific volumes of the solid and liquid respectively. The difference $(p'-p'')$ of the vapour-pressures of the solid and liquid under normal pressure P_0 at a temperature θ near the normal freezing-point θ_0, is deduced from the same equation (see section 24 below)

$$p'-p''=L(\theta-\theta_0)/v\theta_0, \quad . \quad . \quad . \quad (6)$$

where v is the specific volume of the vapour. Substituting for θ in terms of P from (5), we have for the difference of the vapour-pressures at θ_0 under pressure P,

$$p'-p''=(P-P_0)\ (V''-V')/v. \quad . \quad . \quad . \quad (7)$$

The increase of vapour-pressure of the liquid when the pressure is increased to P is given by (2), viz. $p''-p_0=(P-P_0)V''/v$. The increase of vapour-pressure of the solid must be less than that of the liquid by the amount given by (7), in order that their vapour-pressure may be the same at the new freezing-point θ. We thus obtain by subtraction

$$p'-p_0=(P-P_0)\{V''/v-(V''-V')/v\}=(P-P_0)V'/v.$$

Which is precisely the same as relation (2) for the liquid, with V′ substituted for V″. Hence the effect of pressure on the vapour-pressure follows the same law for both liquid and solid (J. H. Poynting, *Phil. Mag.* xii. p. 40, 1881).

7. *Vapour-Pressure of Solutions.*—The rise of boiling-point produced by a substance in solution was demonstrated by M. Faraday in 1820, but the effect had been known to exist for a long time previously. C. H. L. Babo, 1847, gave the law known by his name, that the "relative lowering" $(p-p_0)/p_0$ of the vapour-pressure of a solution, or the ratio of the diminution of vapour-pressure $(p-p_0)$ to the vapour-pressure p_0 of the pure solvent at the same temperature, was constant, or independent of the temperature, for any solution of constant strength. A. Wüllner (*Pogg. Ann.* 1858, 103, p. 529) found the lowering of the vapour-pressure to be nearly proportional to the strength of the solution for the same salt. W. Ostwald, employing Wüllner's results, found the lowering of vapour-pressure produced by different salts in solution in water to be approximately the same for solutions containing the same number of gramme-molecules of salt per c.c. F. M. Raoult (*Comptes Rendus*, 1886–87) employed other solvents besides water, and showed that the relative lowering for different solvents and different dissolved substances was the same in many cases for solutions in which the ratio of the number of gramme-molecules n of the dissolved substance to the number of molecules N of the solvent was the same, or that it varied generally in proportion to the ratio n/N. The relative lowering of the vapour-pressure can be easily measured by Dalton's method of the barometer tube for solvents such as ether, which have a sufficient vapour-pressure at ordinary temperatures. But in many cases it is more readily determined by observing the rise of the boiling-point or the depression of the freezing-point of the solution. For the rise in the boiling-point, we have by Clapeyron's equation, $dp/d\theta=L/\theta v$, nearly, neglecting the volume of the liquid as compared with that of the vapour v. If dp is the difference of vapour-pressure of solvent and solution, and $d\theta$ the rise in the boiling-point, we have the approximate relation,

$$n/N=dp/p=mLd\theta/R\theta^2,\ \text{Raoult's law}, \quad . \quad . \quad (8)$$

where m is the molecular weight of the vapour, and R the gas-constant which is nearly 2 calories per degree for a gramme-molecule of gas. For the depression of the freezing-point a relation of the same form applies, but $d\theta$ is negative, and L is the latent heat of fusion. At the freezing-point, the solution must have the same vapour-pressure as the solid solvent, with which it is in equilibrium. The relation follows immediately from Kirchhoff's expression (below, section 14) for the difference of vapour-pressure of the liquid and solid below the freezing-point.

The most important apparent exceptions to Raoult's law in dilute solutions are the cases, (1) in which the molecules of the dissolved substance in solution are associated to form compound molecules, or dissociated to form other combinations with the solvent, in such a way that the actual number of molecules n in the solution differs from that calculated from the molecular weight corresponding to the accepted formula of the dissolved substance; (2) the case in which the molecules of the vapour of the solvent are associated in pairs or otherwise so that the molecular weight m of the vapour is not that corresponding to its accepted formula. These cases are really included in the equation if we substitute the proper values of n or m. In the case of electrolytes, S. Arrhenius (*Zeit. phys. Chem.* i. p. 631) showed how to calculate the effective number of molecules $n''=(1+ek/k_0)n$, from the molecular conductivity

k of the solution and its value k_0 at infinite dilution, for an electrolyte giving rise to $e+1$ ions. The values thus found agreed in the main with Raoult's law for dilute solutions (see SOLUTIONS). For strong solutions the discrepancies from Raoult's law often become very large, even if dissociation is allowed for. Thus for calcium chloride the depression of the freezing-point, when $n=7$, $N=100$, is nearly 60° C. At this point $n''=10$ nearly, and the depression should be only 10·4° C. These and similar discrepancies have been very generally attributed to a loose and variable association of the molecules of the dissolved substance with molecules of the solvent, which, according to H. C. Jones (*Amer. Chem. Jour.* 1905, 33, p. 584), may vary all the way from a few molecules of water up to at least 30 molecules in the case of $CaCl_2$, or from 12 to 140 for glycerin. It has been shown, however, by Callendar (*Proc. R.S.A.* 1908) that, if the accurate formulae for the vapour-pressure given below are employed, the results for strong solutions are consistent with a very slight, but important, modification of Raoult's law. It is assumed that each molecule of solute combines with a molecules of solvent according to the ordinary law of chemical combination, and that the number a, representing the degree of hydration, remains constant within wide limits of temperature and concentration. In this case the ratio of the vapour-pressure of the solution p'' to that of the solvent p' should be equal to the ratio of the number of free molecules of solvent $N-an$ to the whole number of molecules $N-an+n$ in the solution. The explanation of this relation is that each of the n compound molecules counts as a single molecule, and that, if all the molecules were solvent molecules, the vapour-pressure would be p', that of the pure solvent. This assumption coincides exactly with Raoult's law for the relative lowering of vapour-pressure, if $a=1$, and agrees with it in the limit in all cases for very dilute solutions, but it makes a very considerable difference in strong solutions if a is greater or less than 1. It appears that the relatively enormous deviations of $CaCl_2$ from Raoult's law are accounted for on the hypothesis that $a=9$, but there is a slight uncertainty about the degree of ionization of the strongest solutions at $-50°$ C. Cane-sugar appears to require 5 molecules of water of hydration both at 0° C. and at 100° C., whereas KCl and NaCl take more water at 100° C. than at 0° C. The cases considered by Callendar (*loc. cit.*) are necessarily limited, because the requisite data for strong solutions are comparatively scarce. The vapour-pressure equations are seldom known with sufficient accuracy, and the ionization data are incomplete. But the agreement is very good so far as the data extend, and the theory is really simpler than Raoult's law, because many different degrees of hydration are known, and the assumption $a=1$ (all monohydrates), which is tacitly involved in Raoult's law, is in reality inconsistent with other chemical relations of the substances concerned.

8. *Vapour-Pressure and Osmotic Pressure.*—W. F. P. Pfeffer (*Osmotische Untersuchungen*, Leipzig, 1877) was the first to obtain satisfactory measurements of osmotic pressures of cane-sugar solutions up to nearly 1 atmosphere by means of semi-permeable membranes of copper ferrocyanide. His observations showed that the osmotic pressure was nearly proportional to the concentration and to the absolute temperature over a limited range. Van't Hoff showed that the osmotic pressure P due to a number of dissolved molecules n in a volume V was the same as would be exerted by the same number of gas-molecules at the same temperature in the same volume, or that $PV=R\theta n$. Arrhenius, by reasoning similar to that of section 5, applied to an osmotic cell supporting a column of solution by osmotic pressure, deduced the relation between the osmotic pressure P at the bottom of the column and the vapour-pressure p'' of the solution at the top, viz. $mPV/R\theta = \log_e(p'/p'')$, which corresponds with the effect of hydrostatic pressure, and is equivalent to the assumption that the vapour-pressure of the solution at the bottom of the column under pressure P must be equal to that of the pure solvent. Poynting (*Phil. Mag.* 1896, 42, p. 298) has accordingly defined the osmotic pressure of a solution as being the hydrostatic pressure required to make its vapour-pressure equal to that of the pure solvent at the same temperature, and has shown that this definition agrees approximately with Raoult's law and van't Hoff's gas-pressure theory. It is probable that osmotic pressure is not really of the same nature as gas-pressure, but depends on equilibrium of vapour-pressure. The vapour-molecules of the solvent are free to pass through the semi-permeable membrane, and will continue to condense in the solution until the hydrostatic pressure is so raised as to produce equality of vapour-pressure. Lord Berkeley and E. J. G. Hartley (*Phil. Trans.* A. 1906, p. 481) succeeded in measuring osmotic pressures of cane-sugar, dextrose, &c., up to 135 atmospheres. The highest pressures recorded for cane-sugar are nearly three times as great as those given by van't Hoff's formula for the gas-pressure, but agree very well with the vapour-pressure theory, as modified by Callendar, provided that we substitute for V in Arrhenius's formula the actual specific volume of the solvent in the solution, and if we also assume that each molecule of sugar in solution combines with 5 molecules of water, as required by the observations on the depression of the freezing-point and the rise of the boiling-point. Lord Berkeley and Hartley have also verified the theory by direct measurements of the vapour-pressures of the same solutions.

9. *Total Heat and Latent Heat.*—To effect the conversion of a solid or liquid into a vapour without change of temperature, it is necessary to supply a certain quantity of heat. The quantity required per unit mass of the substance is termed the *latent heat of vaporization.* The *total heat* of the saturated vapour at any temperature is usually defined as the quantity of heat required to raise unit mass of the liquid from any convenient zero up to the temperature considered, and then to evaporate it at that temperature under the constant pressure of saturation. The total heat of steam, for instance, is generally reckoned from the state of water at the freezing-point, 0° C. If h denote the heat required to raise the temperature of the liquid from the selected zero to the temperature $t°$ C., and if H denote the total heat and L the latent heat of the vapour, also at $t°$ C., we have evidently the simple relation

$$H=L+h. \quad . \quad . \quad . \quad . \quad (9)$$

The pressure under which the liquid is heated makes very little difference to the quantity h, but, in order to make the statement definite, it is desirable to add that the liquid should be heated under a constant pressure equal to the final saturation-pressure of the vapour. The usual definition of total heat applies only to a saturated vapour. For greater simplicity and generality it is desirable to define the total heat of a substance as the function $(E+pv)$, where E is the intrinsic energy and v the volume of unit mass (see THERMODYNAMICS). This agrees with the usual definition in the special case of a saturated vapour, if the liquid is heated under the final pressure p, as is generally the case in heat engines and in experimental measurements of H.

The method commonly adopted in measuring the latent heat of a vapour is to condense the vapour at saturation-pressure in a calorimeter. The quantity of heat so measured is the total heat of the vapour reckoned from the final temperature of the calorimeter, and the heat of the liquid h must be subtracted from the total heat measured to find the latent heat of the vapour at the given temperature. It is necessary to take special precautions to ensure that the vapour is dry or free from drops of liquid. Another method, which is suitable for volatile liquids or low temperatures, is to allow the liquid to evaporate in a calorimeter, and to measure the quantity of heat required for the evaporation of the liquid at the temperature of the calorimeter and at saturation-pressure. The first method may be called the method of condensation. It was applied in the most perfect manner by Regnault to determine the latent heats of steam and several other vapours at high pressures. The second method may be called the method of evaporation. It is more difficult of application than the first, but has given some good results in the hands of Griffiths[1] and Dieterici, although the experiments of Regnault by this method were not very successful.

It was believed for many years, in consequence of some rough experiments made by J. Watt, that the total heat of steam was constant. This was known as Watt's law, and was sometimes extended to other vapours. An alternative supposition, due to J. Southern, was that the latent heat was constant. The very careful experiments of Regnault, published in 1847, showed that the truth lay somewhere between the two. The formula which he gave for the total heat H of steam at any temperature $t°$ C., which has since been universally accepted and has formed the basis of all tables of the properties of steam, was as follows:—

$$H=606{\cdot}5+0{\cdot}305t. \quad . \quad . \quad . \quad (10)$$

He obtained similar formulae for other vapours, but the experiments were not so complete or satisfactory as in the case of steam, which may conveniently be taken as a typical vapour in comparing theory and experiment.

10. *Total Heat of Ideal Vapour.*—It was proved theoretically by W. J. M. Rankine (*Proc. R.S.E.* vol. xx. p. 173) that the increase of the total heat of a saturated vapour between any two temperatures should be equal to the specific heat S of the vapour at constant pressure multiplied by the difference of temperature, provided that the saturated vapour behaved as an ideal gas, and that its specific heat was independent of the pressure and temperature. Expressed in symbols, the relation may be written

$$H'-H''=S(\theta'-\theta''). \quad . \quad . \quad . \quad (11)$$

This relation gives a linear formula for the variation of the total heat, a result which agrees in form with that found by Regnault for steam, and implies that the coefficient of t in his formula should be equal to the specific heat S of steam. Rankine's equation follows directly from the first law of thermodynamics, and may be proved as follows: The heat absorbed in any transformation is the change of intrinsic energy *plus* the external work done. To find the total heat H of a vapour, we have $H=E+p(v-b)$, where the intrinsic energy E is measured from the selected zero θ_0 of total heat. The external work done is $p(v-b)$, where p is the constant pressure, v the volume of the vapour at θ, and b the volume of the liquid at θ_0. If the saturated vapour behaves as a perfect gas, the change of intrinsic energy E depends only on the temperature limits, and is equal to $s(\theta-\theta_0)$, where s is the specific heat at constant volume. Taking the difference between the values of H for any two temperatures

[1] "Latent Heat of Steam," *Phil. Trans.* A. 1895; of "Benzene," *Phil. Mag.* 1896.

θ' and θ'', we see that Rankine's result follows immediately, provided that $p(v-b)$ is equal to $(S-s)\theta$ or $R\theta/m$, which is approximately true for gases and vapours when v is very large compared with b. We may observe that the equation (11) is accurately true for an ideal vapour, for which $pv=(S-s)\theta$, provided that the total heat is defined as equal to the change of the function $(E+pv)$ between the given limits. Adopting this definition, without restriction to the case of an ideal vapour or to saturation-pressure, the rate of variation of the total heat with temperature $(dH/d\theta)$ at constant pressure is equal to S under all conditions, whether S is constant, or varies both with p and θ. (See THERMODYNAMICS, § 7.)

11. *Specific Heat of Vapours.*—The question of the measurement of the specific heat of a vapour possesses special interest on account of this simple theoretical relation between the specific heat and the variation of the latent and total heats. The first accurate calculations of the specific heats of air and gases were made by Rankine in a continuation of the paper already quoted. Employing Joule's value of the mechanical equivalent of heat, then recently published, in connexion with the value of the ratio of the specific heats of air $S/s=1{\cdot}40$ deduced from the velocity of sound, Rankine found for air $S=\cdot240$, which was much smaller than the best previous determinations (*e.g.* Delaroche and Berard, $S=\cdot267$), but agreed very closely with the value $S=\cdot238$, found by Regnault at a later date. Adopting for steam the same value of the ratio of the specific heats, viz. 1·40, Rankine found $S=\cdot385$, a value which he used, in default of a better, in calculating some of the properties of steam, although he observed that it was much larger than the coefficient ·305 in Regnault's formula for the variation of the total heat. The specific heat of steam was determined shortly afterwards by Regnault (*Comptes Rendus*, 36, p. 676) by condensing superheated steam at two different temperatures (about 125° and 225° C.) successively in the same calorimeter at atmospheric pressure, and taking the difference of the total heats observed. The result found in this manner, viz. $S=\cdot475$, greatly increased the apparent discrepancy between Regnault's and Rankine's formulae for the total heat. The discrepancy was also noticed by G. R. Kirchhoff, who rediscovered Rankine's formula (*Pogg. Ann.* 103, p. 185, 1858). He suggested that the high value for S found by Regnault might be due to the presence of damp in his superheated steam, or, on the other hand, that the assumption that steam at low temperatures followed the law $pv=R\theta$ might be erroneous. These suggestions have been frequently repeated, but it is probable that neither is correct. G. A. Zeuner, at a later date (*La Chaleur*, p. 441), employing the empirical formula $pv=B\theta+Cp^{\cdot25}$ for saturated steam, found the value $S=\cdot568$, which further increased the discrepancy. G. A. Hirn and A. A. Cazin (*Ann. Chim. Phys.* iv. 10, p. 349, 1867) investigated the form of the adiabatic for steam passing through the state $p=760$ mm., $\theta=373°$ Abs., by observing the pressure of superheated steam at any temperature which just failed to produce a cloud on sudden expansion to atmospheric pressure. Assuming an equation of the form $\log(p/760)=a\log(\theta/373)$, their results give $a=S/R=4{\cdot}305$, or $S=0{\cdot}474$, which agrees very perfectly with Regnault's value. It must be observed, however, that the agreement is rather more perfect than the comparative roughness of the method would appear to warrant. More recently, Macfarlane Gray (*Proc. Inst. Mech. Eng.* 1889), who has devoted minute attention to the reduction of Regnault's observations, assuming $S/s=1{\cdot}400$ as the theoretical ratio of specific heats of all vapours on his "aether-pressure theory," has calculated the properties of steam on the assumption $S=0{\cdot}384$. He endeavours to support this value by reference to sixteen of Regnault's observations on the total heat of steam at atmospheric pressure with only 19° to 28° of superheat. These observations give values for S ranging from 0·30 to 0·46, with a mean value 0·3778. But it must be remarked that the superheat of the steam in these experiments is only 1 or 2 % of the total heat measured. A similar objection applies, though with less force, to Regnault's main experiments between 125° and 225° C., giving the value $S=0{\cdot}475$, in which the superheat (on which the value of S depends) is only one-sixteenth of the total heat measured. Gray explains the higher value found by Regnault over the higher range as due to the presence of particles of moisture in the steam, which he thinks "would not be evaporated up to 124° C., but would be more likely to be evaporated in the higher range of temperature." J. Perry (*Steam Engine*, p. 580), assuming a characteristic equation similar to Zeuner's (which makes v a linear function of the temperature at constant pressure, and S independent of the pressure), calculates S as a function of the temperature to satisfy Regnault's formula (10) for the total heat. This method is logically consistent, and gives values ranging from 0·305 at 0° to 0·341 at 100° C. and 0·464 at 210° C., but the difference from Regnault's $S=0{\cdot}475$ cannot easily be explained.

12. *Throttling Calorimeter Method.*—The ideal method of determining by direct experiment the relation between the total heat and the specific heat of a vapour is that of Joule and Thomson, which is more commonly known in connexion with steam as the method of the throttling calorimeter. It was first employed in the case of steam by Peabody as a means of estimating the wetness of saturated steam, which is an important factor in testing the performance of an engine. If steam or vapour is "wire-drawn" or expanded through a porous plug or throttling aperture without external loss or gain of heat, the total heat $(E+pv)$ remains constant (THERMODYNAMICS, § 11), provided that the experiment is arranged so that the kinetic energy of flow is the same on either side of the throttle. Thus, starting with saturated steam at a temperature θ' and pressure p', as represented by the point A on the $p\theta$ diagram (fig. 2), if the point B represent the state $p''\theta''$ after passing the throttle, the total heat at A is the same as that at B, and exceeds that at any other point D (at the same pressure p'' as at B, but at a lower temperature θ) by the amount $S\times(\theta''-\theta)$, which would be required to raise the temperature from D to B at constant pressure. We have therefore the simple relation between the total heats at A and D—

$$H_A-H_D=S(\theta''-\theta). \quad (12)$$

If the steam at A contains a fraction z of suspended moisture, the total heat H_A is less than the value for dry saturated steam at A by the amount zL. If the steam at A were dry and saturated, we should have, assuming Regnault's formula (10), $H_A-H_D=\cdot305\,(\theta'-\theta)$, whence, if $S=\cdot475$, we have $zL=\cdot305\,(\theta'-\theta)-\cdot475\,(\theta''-\theta)$. It is evident that this is a very delicate method of determining the wetness z, but, since with dry saturated steam at low pressures this formula always gives *negative* values of the wetness, it is clear that Regnault's numerical coefficients must be wrong.

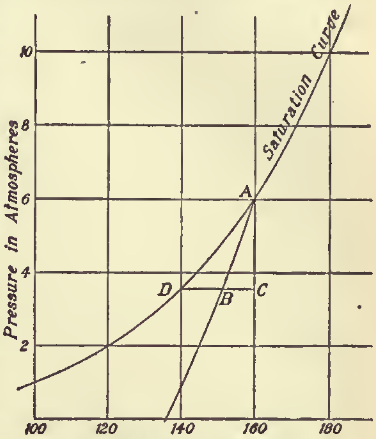

FIG. 2.—Throttling Calorimeter Method.

From a different point of view, equation (12) may be applied to determine the specific heat of steam in terms of the rate of variation of the total heat. If we assume Regnault's formula (10) for the total heat, we have evidently the simple relation $S=0{\cdot}305(\theta'-\theta)/(\theta''-\theta)$, supposing the initial steam to be dry, or at least of the same quality as that employed by Regnault. This method was applied by J. A. Ewing (*B.A. Rep.* 1897) to steam near 100° C. He found the specific heat smaller than 0·475, but no numerical results were given. A very complete investigation on the same lines was carried out by J. H. Grindley (*Phil. Trans.* 1900) at Owens College under the direction of Osborne Reynolds. Assuming $dH/d\theta=0{\cdot}305$ for saturated steam, he found that S was nearly independent of the pressure at constant temperature, but that it varied with the temperature from 0·387 at 100° C. to 0·665 at 160° C. Writing Q for the Joule-Thomson "cooling effect," $d\theta/dp$, or the slope BC/AC of the line of constant total heat, he found that Q was nearly independent of the pressure at constant temperature, a result which agrees with that of Joule and Thomson for air and CO_2; but that it varied with the temperature as $(1/\theta)^{3.8}$ instead of $(1/\theta)^2$. These results for the variation of Q are independent of any assumption with regard to the variation of H. Employing the values of S calculated from $dH/d\theta=0{\cdot}305$, he found that the product SQ was independent of both pressure and temperature for the range of his experiments. Assuming this result to hold generally, we should have $S=0{\cdot}306$ at 0° C., which agrees with Rankine's view; but increasing very rapidly at higher temperatures to $S=1{\cdot}043$ at 200° C., and 1·315 at 220° C. The characteristic equation, if SQ=constant, would be of the form $(v+SQ)=R\theta/p$, which does not agree with the well-known behaviour of other gases and vapours. Whatever may be the objections to Regnault's method of measuring the specific heat of a vapour, it seems impossible to reconcile so wide a range of variation of S with his value $S=0{\cdot}475$ between 125° and 225° C. It is also extremely unlikely that a vapour which is so stable a chemical compound as steam should show so wide a range of variation of specific heat. The *experimental* results of Grindley with regard to the mode of variation of Q have been independently confirmed by Callendar (*Proc. R.S.* 1900), who quotes the results of similar experiments made at McGill College in 1897, but gives an entirely different interpretation, based on a direct measurement of the specific heat at 100° C. by an electrical method.

The method of deducing the specific heat from Regnault's formula for the variation of the total heat is evidently liable in a greater degree to the objections which have been urged against his method of determining the specific heat, since it makes the value of the specific heat depend on small differences of total heat observed under conditions of greater difficulty at various pressures. The more logical method of procedure is to determine the specific heat independently of the total heat, and then to deduce the variations of total heat by equation (12). The simplest method of measuring the specific heat appears to be that of supplying heat electrically to a steady current of vapour in a vacuum-jacket calorimeter, and observing the rise of temperature produced. Employing this method, Callendar finds $S=0{\cdot}497$ for steam at one atmosphere between 103° C. and 113° C. This is about 4% larger than Regnault's value, but is not really inconsistent with it, if we suppose that the specific heat at any given pressure diminishes slightly with rise of temperature, as indicated in formula (16) below.

13. *Corrected Equation of Total Heat.*—Admitting the value $S=0\cdot497$ for the specific heat at 108° C., it is clear that the form of Regnault's equation (10) must be wrong, although the numerical value of the coefficient 0·305 may approximately represent the average rate of variation over the range (100° to 190° C.) of the experiments on which it chiefly depends. Regnault's experiments at lower temperatures were extremely discordant, and have been shown by the work of E. H. Griffiths (*Proc. R.S.* 1894) and C. H. Dieterici (*Wied. Ann.* 37, p. 504, 1889) to give values of the total heat 10 to 6 calories too large between 0° and 40° C. At low pressures and temperatures it is probable that saturated steam behaves very nearly as an ideal gas, and that the variation of the total heat is closely represented by Rankine's equation with the ideal value of S. In order to correct this equation for the deviations of the vapour from the ideal state at higher temperatures and pressures, the simplest method is to assume a modified equation of the Joule-Thomson type (THERMODYNAMICS, equation (17)), which has been shown to represent satisfactorily the behaviour of other gases and vapours at moderate pressures. Employing this type of equation, all the thermodynamical properties of the substance may conveniently be expressed in terms of the diminution of volume c due to the formation of compound or coaggregated molecules,

$$(v-b)=R\theta/p-c_0(\theta_0/\theta)^n=V-c. \quad . \quad . \quad (13)$$

The index n in the above formula, representing the rate of variation of c with temperature, is approximately the same as that expressing the rate of variation of the cooling effect Q, which is nearly proportional to c, and is given by the formula

$$SQ=(n+1)c-b. \quad . \quad . \quad . \quad . \quad (14)$$

The corresponding formula for the total heat is

$$H-H_0=S_0(\theta-\theta_0)-(n+1)\ (cp-c_0p_0)+b(p-p_0), \quad . \quad (15)$$

and for the variation of the specific heat with pressure

$$S=S_0+n(n+1)pc/\theta, \quad . \quad . \quad . \quad (16)$$

where S_0 is the value of S when $p=0$, and is assumed to be independent of θ, as in the case of an ideal gas.

Callendar's experiments on the cooling effect for steam by the throttling calorimeter method gave $n=3\cdot33$ and $c=26\cdot3$ c.c. at 100° C. Grindley's experiments gave nearly the same average value of Q over his experimental range, but a rather larger value for n, namely, 3·8. For purposes of calculation, Callendar (*Proc. R.S.* 1900) adopted the mean value $n=3\cdot5$, and also assumed the specific heat at constant volume $s=3\cdot5$ R (which gives $S_0=4\cdot5$ R) on the basis of an hypothesis, doubtfully attributed to Maxwell, that the number of degrees of freedom of a molecule with m atoms is $2m+1$. The assumption $n=s/R$ simplifies the adiabatic equation, but the value $n=3\cdot5$ gives $S_0=0\cdot497$ at zero pressure, which was the value found by Callendar experimentally at 108° C. and 1 atmosphere pressure. Later and more accurate experiments have confirmed the experimental value, and have shown that the limiting value of the specific heat should consequently be somewhat smaller than that given by Maxwell's hypothesis. The introduction of this correction into the calculations would slightly improve the agreement with Regnault's values of the specific heat and total heat between 100° and 200° C., where they are most trustworthy, but would not materially affect the general nature of the results.

Values calculated from these formulae are given in the table below. The values of H at 0° and 40° agree fairly with those found by Dieterici (596·7) and Griffiths (613·2) respectively, but differ considerably from Regnault's values 606·5 and 618·7. The rate of increase of the total heat, instead of being constant for saturated steam as in Regnault's formula, is given by the equation

$$dH/d\theta=S(1-Qdp/d\theta) \quad . \quad . \quad . \quad (17)$$

and diminishes from 0·478 at 0° C. to about 0·40 at 100° and 0·20 at 200° C., decreasing more rapidly at higher temperatures. The mean value, 0·313 of $dH/d\theta$, between 100° and 200° agrees fairly well with Regnault's coefficient 0·305, but it is clear that considerable errors in calculating the wetness of steam or the amount of cylinder condensation would result from assuming this important coefficient to be constant. The rate of change of the latent heat is easily deduced from that of the total heat by subtracting the specific heat of the liquid. Since the specific heat of the liquid increases rapidly at high temperatures, while $dH/d\theta$ diminishes, it is clear that the latent heat must diminish more and more rapidly as the critical point is approached. Regnault's formula for the total heat is here again seen to be inadmissible, as it would make the latent heat of steam vanish at about 870° C. instead of at 365° C. It should be observed, however, that the assumptions made in deducing the above formulae apply only for moderate pressures, and that the formulae cannot be employed up to the critical point owing to the uncertainty of the variation of the specific heats and the cooling effect Q at high pressures beyond the experimental range. Many attempts have been made to construct formulae representing the deviations of vapours from the ideal state up to the critical point. One of the most complete is that proposed by R. J. E. Clausius, which may be written

$$R\theta/p-v=R\theta(v-b)(A-B\theta^n)/p(v+a)^2\theta_n; \quad . \quad (18)$$

but such fomulae are much too complicated to be of any practical use, and are too empirical in their nature to permit of the direct physical interpretation of the constants they contain.

14. *Empirical Formulae for the Saturation-Pressure.*—The values of the saturation-pressure have been very accurately determined for the majority of stable substances, and a large number of empirical formulae have been proposed to represent the relation between pressure and temperature. These formulae are important on account of the labour and ingenuity expended in devising the most suitable types, and also as a convenient means of recording the experimental data. In the following list, which contains a few typical examples, the different formulae are arranged to give the logarithm of the saturation-pressure p in terms of the absolute temperature θ. As originally proposed, many of these formulae were cast in exponential form, but the adoption of the logarithmic method of expression throughout the list serves to show more clearly the relationship between the various types.

$\log p=A+B\theta$	(Dalton, 1800).	(19)
$\log p=C\log(A+B\theta)$	(Young, 1820).	
$\log p=A\theta/(B+C\theta)$	(Roche, 1830).	
$\log p=A+Bb^\theta+Cc^\theta$	(Biot, 1844; Regnault).	
$\log p=A+B/\theta+C/\theta^2$	(Rankine, 1849).	
$\log p=A+B/\theta+C\log\theta$	(Kirchhoff, 1858; Rankine, 1866).	
$\log p=A+B/\theta^b$	(Unwin, 1887).	
$\log p=A+B\log\theta+C\log(\theta+c)$	(Bertrand, 1887).	
$\log p=A+B/(\theta+C)$	(Antoine, 1888).	

The formula of Dalton would make the pressure increase in geometrical progression for equal increments of temperature. In other words, the increase of pressure per degree ($dp/d\theta$) divided by p should be constant and equal to B; but observation shows that this ratio decreases, *e.g.* from 0·0722 at 0° C. to 0·0357 at 100° C. in the case of steam. Observing that this rate of diminution is approximately as the square of the reciprocal of the absolute temperature, we see that the almost equally simple formula $\log p=A+B/\theta$ represents a much closer approximation to experiment. As a matter of fact, the two terms $A+B/\theta$ are the most important in the theoretical expression for the vapour-pressure given below. They are not sufficient alone, but give good results when modified, as in the simple and accurate formulae of Rankine, Kirchhoff, L. C. Antoine and Unwin. If we assume formulae of the simple type $A+B/\theta$ for *two different substances* which have the same vapour-pressure p at the absolute temperatures θ' and θ'' respectively, we may write

$$\log p=A'+B'/\theta'=A''+B''/\theta'', \quad . \quad . \quad (20)$$

from which we deduce that the ratio θ'/θ'' of the temperatures at which the vapour-pressures are the same is a linear function of the temperature θ' of one of the substances. This approximate relation has been employed by Ramsay and Young (*Phil. Mag.* 1887) to deduce the vapour-pressures of any substance from those of a standard substance by means of two observations. More recently the same method has been applied by A. Findlay (*Proc. R.S.* 1902), under Ramsay's direction, for comparing solubilities which are in many respects analogous to vapour-pressures. The formulae of Young and Roche are purely empirical, but give very fair results over a wide range. That of Biot is far more complicated and troublesome, but admits greater accuracy of adaptation, as it contains five constants (or six, if θ is measured from an arbitrary zero). It is important as having been adopted by Regnault (and also by many subsequent calculators) for the expression of his observations on the vapour-pressures of steam and various other substances. The formulae of Rankine and Unwin, though probably less accurate over the whole range, are much simpler and more convenient in practice than that of Biot, and give results which suffice in accuracy for the majority of purposes.

15. *Theoretical Equation for the Saturation-Pressure.*—The empirical formulae above quoted must be compared and tested in the light of the theoretical relation between the latent heat and the rate of increase of the vapour-pressure ($dp/d\theta$), which is given by the second law of thermodynamics, viz.

$$\theta(dp/d\theta)=L/(v-w), \quad . \quad . \quad . \quad (21)$$

in which v and w are the volumes of unit mass of the vapour and liquid respectively at the saturation-point (THERMODYNAMICS, § 4). This relation cannot be directly integrated, so as to obtain the equation for the saturation-pressure, unless L and $v-w$ are known as functions of θ. Since it is much easier to measure p than either L or v, the relation has generally been employed for deducing either L or v from observations of p. For instance, it is usual to calculate the specific volumes of saturated steam by assuming Regnault's formulae for p and L. The values so found are necessarily erroneous if formula (10) for the total heat is wrong. The reason for adopting this method is that the specific volume of a saturated vapour cannot be directly measured with sufficient accuracy on account of the readiness with which it condenses on the surface of the containing vessel. The specific volumes of superheated vapours may, however, be measured with a satisfactory degree of approximation. The deviations from the ideal volume may also be deduced by the method of Joule and Thomson. It is found by these methods that the behaviour of superheated vapours closely resembles that of non-condensible gases, and it is a fair inference that similar behaviour would be observed up to the saturation-point if surface condensation could be avoided. By assuming suitable forms of the characteristic equation to represent the variations of the specific volume within certain limits of pressure and temperature, we may therefore with propriety deduce equations to represent the saturation-pressure, which will certainly be thermodynamically consistent, and will probably give correct numerical results within the assigned limits.

The simplest assumptions to make are that the vapour behaves as a perfect gas (or that $p(v-w)=R\theta$), and that L is constant. This leads immediately to the simple formula

$$\log_e(p/p_0)=(1/\theta_0-1/\theta)L/R, \quad . \quad . \quad . \quad (22)$$

which is of the same type as $\log p=A+B/\theta$, and shows that the coefficient B should be equal to L/R. A formula of this type has been widely employed by van't Hoff and others to calculate heats of reaction and solution from observations of solubility and vice versa. It is obvious, however, that the assumption L = constant is not sufficiently accurate in many cases. The rate of variation of the latent heat at low pressures is equal to $S-s$, where s is the specific heat of the liquid. Under these conditions both S and s may be regarded as approximately constant, so that L is a linear function of the temperature. Substituting $L=L_0+(S-s)(\theta-\theta_0)$, and integrating between limits, we obtain the result

$$\log_e p=A+B/\theta+C\log_e\theta, \quad . \quad . \quad . \quad (23)$$

where

$$C=(S-s)/R,\ B=-[L_0+(s-S)\theta_0]/R,$$

and

$$A=\log_e p_0-B/\theta_0-C\log_e\theta_0.$$

A formula of this type was first obtained by Kirchhoff (*Pogg. Ann.* 103, p. 185, 1858) to represent the vapour-pressure of a solution, and was verified by Regnault's experiments on solutions of H_2SO_4 in water, in which case a constant, the heat of dilution, is added to the latent heat. The formula evidently applies to the vapour-pressure of the pure solvent as a special case, but Kirchhoff himself does not appear to have made this particular application of the formula. In the paper which immediately follows, he gives the oft-quoted expression for the difference of slope $(dp/d\theta)_s-(dp/d\theta)_l$ of the vapour-pressure curves of a solid and liquid at the triple point, which is immediately deducible from (21), viz.

$$\theta(dp/d\theta)_s-\theta(dp/d\theta)_l=(L_s-L_l)/(v-w)=L_f/(v-w), \quad (24)$$

in which L_s and L_l are the latent heats of vaporization of the solid and liquid respectively, the difference of which is equal to the latent heat of fusion L_f. He proceeds to calculate from this expression the difference of vapour-pressures of ice and water in the immediate neighbourhood of the melting-point, but does not observe that the vapour-pressures themselves may be more accurately calculated for a considerable interval of temperature by means of formula (23), by substituting the appropriate values of the latent heats and specific heats. Taking for ice and water the following numerical data, $L_s=674{\cdot}7$, $L_l=595{\cdot}2$, $L_f=79{\cdot}5$, $R=0{\cdot}1103$ cal./deg., $p_0=4{\cdot}61$ mm., $s-S={\cdot}519$ cal./deg., and assuming the specific heat of ice to be equal to that of steam at constant pressure (which is sufficiently approximate, since the term involving the difference of the specific heats is very small), we obtain the following numerical formulae, by substitution in (23),

Ice . . $\log_{10}p=0{\cdot}6640+9{\cdot}73t/\theta$,
Water . $\log_{10}p=0{\cdot}6640+8{\cdot}585t/\theta-4{\cdot}70(\log_{10}\theta/\theta_0-Mt/\theta)$,

where $t=\theta-273$, and $M=0{\cdot}4343$, the modulus of common logarithms. These formulae are practically accurate for a range of 20° or 30° C. on either side of the melting-point, as the pressure is so small that the vapour may be treated as an ideal gas. They give the following numerical values:—

Temperature, C.	−20°	−10°	0°	+10°	+20°
V.P. of ice, mms.	0·79	1·97	4·61	10·20	21·27
V.P. of water, mms.	0·96	2·17	4·61	9·27	17·58

The error of the formula for water is less than 1 mm. (or a tenth of a degree C.), at a temperature so high as 60° C.

Formula (23) for the vapour-pressure was subsequently deduced by Rankine (*Phil. Mag.* 1866) by combining his equation (11) for the total heat of gasification with (21), and assuming an ideal vapour. A formula of the same type was given by Athenase Dupré (*Théorie de chaleur*, p. 96, Paris, 1869), on the assumption that the latent heat was a linear function of the temperature, taking the instance of Regnault's formula (10) for steam. It is generally called Dupré's formula in continental text-books, but he did not give the values of the coefficients in terms of the difference of specific heats of the liquid and vapour. It was employed as a purely empirical formula by Bertrand and Barus, who calculated the values of the coefficients for several substances, so as to obtain the best general agreement with the results of observation over a wide range, at high as well as low pressures. Applied in this manner, the formula is not appropriate or satisfactory. The values of the coefficients given by Bertrand, for instance, in the formula for steam, correspond to the values $S={\cdot}576$ and $L=573$ at 0° C., which are impossible, and the values of p given by his formula (*e.g.* 763 mm. at 100° C.) do not agree sufficiently with experiment to be of much practical value. The true application of the formula is to low pressures, at which it is very accurate. The close agreement found under these conditions is a very strong confirmation of the correctness of the assumption that a vapour at low pressures does really behave as an ideal gas of constant specific heat. The formula was independently rediscovered by H. R. Hertz (*Wied. Ann.* 17, p. 177, 1882) in a slightly different form, and appropriately applied to the calculation of the vapour-pressures of mercury at ordinary temperatures, where they are much too small to be accurately measured.

16. *Corrected Equation of Saturation-Pressure.*—The approximate equation of Rankine (23) begins to be 1 or 2% in error at the boiling-point under atmospheric pressure, owing to the coaggregation of the molecules of the vapour and the variation of the specific heat of the liquid. The errors from both causes increase more rapidly at higher temperatures. It is easy, however, to correct the formula for these deviations, and to make it thermodynamically consistent with the characteristic equation (13) by substituting the appropriate values of $(v-w)$ and $L=H-h$ from equations (13) and (15) in formula (21) before integrating. Omitting w and neglecting the small variation of the specific heat of the liquid, the result is simply the addition of the term $(c-b)/V$ to formula (23)

$$\log p=A+B/\theta+C\log\theta+(c-b)/V. \quad . \quad . \quad (25)$$

The values of the coefficients B and C remain practically as before. The value of c is determined by the throttling experiments, so that all the coefficients in the formula with the exception of A are determined independently of any observations of the saturation-pressure itself. The value of A for steam is determined by the consideration that $p=760$ mm. by definition at 100° C. or 373° Abs. The most uncertain data are the variation of the specific heat of the liquid and the value of the small quantity b in the formula (13). The term b, however, is only 4% of c at 100° C., and the error involved in taking b equal to the volume of the liquid is probably small. The effect of variation of the specific heat is more important, but is nearly eliminated by the form of the equation. If we write $h=s_0t+dh$, where s_0 is a selected constant value of the specific heat of the liquid, and dh represents the difference of the actual value of h at t from the ideal value s_0t, and if we similarly write $\phi=s_0\log_e(\theta/\theta_0)+d\phi$ for the entropy of the liquid at t, where $d\phi$ represents the corresponding difference in the entropy (which is easily calculated from a table of values of h), it is shown by Callendar (*Proc. R.S.* 1900, *loc. cit.*) that the effect of the variation of the specific heat of the liquid is represented in the equation for the vapour-pressure by adding to the right-hand side of (23) the term $-(d\phi-dh/\theta)/R$. If we proceed instead by the method of integrating the equation $H-h=\theta(v-w)dp/d\theta$, we observe that the expression above given results from the integration of the terms $-dh/R\theta^2+w(dp/d\theta)/R\theta$, which were omitted in (25). Adopting the formula of Regnault as corrected by Callendar (*Phil. Trans. R.S.* 1902) for the specific heat of water between 100° and 200° C., we find the values of the difference $(d\phi-dh/\theta)$ to be less than one-tenth of $d\phi$ at 200° C. The whole correction is therefore probably of the same order as the uncertainty of the variation of the specific heat itself at these temperatures. It may be observed that the correction would vanish if we could write $dh=w\theta dp/d\theta=wL/(v-w)$. This assumption is made by Gray (*Proc. Inst. C.E.* 1902). It is equivalent, as Callendar (*loc. cit.*) points out, to supposing that the variation of the specific heat is due to the formation and solution of a mass $w/(v-w)$ of vapour molecules per unit mass of the liquid. But this neglects the latent heat of solution, unless we may suppose it included by writing the internal latent heat L_i in place of L in Callendar's formula. In any case the correction may probably be neglected for practical purposes below 200° C.

It is interesting to remark that the simple result found in equation (25) (according to which the effect of the deviation of the vapour from the ideal state is represented by the addition of the term $(c-b)/V$ to the expression for $\log p$) is independent of the assumption that c varies inversely as the n^{th} power of θ, and is true generally provided that $c-b$ is a function of the temperature only and is independent of the pressure. But in order to deduce the values of c by the Joule-Thomson method, it is necessary to assume an empirical formula, and the type $c=c_0(\theta_0/\theta)^n$ is chosen as being the simplest. The justification of this assumption lies in the fact that the values of c found in this manner, when substituted in equation (25) for the saturation-pressure, give correct results for p within the probable limits of error of Regnault's experiments.

17. *Numerical Application to Steam.*—As an instance of the application of the method above described, the results in the table below are calculated for steam, starting from the following fundamental data: $p=760$ mm. at $t=100°$ C. or 373·0° Abs. $pV/\theta=0{\cdot}11030$ calories per degree for ideal steam. $S_0=0{\cdot}478$ calories per degree at zero pressure, $L=540{\cdot}2$ calories at 100° C. (Joly-Callendar), $n=3{\cdot}33$, $c_{100}=26{\cdot}30$ c.c., $b=1$ c.c., $h=0{\cdot}9970t+wL(v-w)$. 750 mm. Hg. = 1 megadyne per sq. cm.

TABLE OF PROPERTIES OF SATURATED STEAM [1]

Temp. Cent.	Coaggregation, c, cub. cms.	Total Heat, H, calories.	Latent Heat, L, calories.	Specific Heat, S, cals./deg.	Saturation-Pressure, p, mm. of Hg.
0°	74·43	595·2	595·2	·4786	4·6
20°	58·81	604·7	584·7	·4796	17·6
40°	47·19	614·0	574·0	·4818	55·4
60°	38·68	623·1	536·1	·4860	149·4
80°	31·60	631·9	551·9	·4926	355·0
100°	26·30	640·3	540·2	·5027	760·0
120°	21·93	648·1	527·8	·5163	1490·4
140°	18·73	655·1	514·5	·5347	2715·8
160°	16·00	661·4	500·3	·5571	4647
180°	13·76	666·9	485·3	·5834	7534
200°	11·92	671·6	469·3	·6134	11660

The values of the coaggregation-volume c, which form the starting-point of the calculation, are found by taking $n=10/3$ for convenience of division in formula (13). The unit of heat assumed in the table is the calorie at 20° C., which is taken as equal to 4·180 joules, as explained in the article CALORIMETRY. The latent heat L (formula 9) is found by subtracting from H (equation 15) the values of the heat of the liquid h given in the same article. The values of the specific heat in the next column are calculated for a constant pressure equal to that of saturation by formula (16) to illustrate the increase of the specific heat with rise of pressure. The specific heat at any given pressure diminishes with rise of temperature. The values of the saturation-pressure given in the last column are calculated by formula (25), which agrees with Regnault's observations better than his own empirical formulae. The agreement of the values of H with those of Griffiths and Dieterici at low temperatures, and of the values of p with those of Regnault over the whole range, are a confirmation of the accuracy of the foregoing theory, and show that the behaviour of a vapour like steam may be represented by a series of thermodynamically consistent formulae, on the assumption that the limiting value of the specific heat is constant, and that the isothermals are generally similar in form to those of other gases and vapours at moderate pressures. Although it is not possible to represent the properties of steam in this manner up to the critical temperature, the above method appears more satisfactory than the adoption of the inconsistent and purely empirical formulae which form the basis of most tables at the present time.

A similar method of calculation might be applied to deduce the thermodynamical properties of other vapours, but the required experimental data are in most cases very imperfect or even entirely wanting. The calorimetric data are generally the most deficient and difficult to secure. An immense mass of material has been collected on the subject of vapour-pressures and densities, the greater part of which will be found in Winkelmann's *Handbook*, in Landolt's and Bornstein's *Tables*, and in similar compendiums. The results vary greatly in accuracy, and are frequently vitiated by errors of temperature measurement, by chemical impurities and surface condensation, or by peculiarities of the empirical formulae employed in smoothing the observations; but it would not be within the scope of the present article to discuss these details. Even at the boiling-points the discrepancies between different observers are frequently considerable. The following table contains the most probable values for a few of these points which have been determined with the greatest care or frequency:—

Table of Boiling-Points at Atmospheric Pressure on Centigrade Scale

Hydrogen	−252°·6	Benzophenone	+305°·8
Oxygen	−182°·8	Mercury	+356°·7
Carbon dioxide	− 78°·3	Sulphur	+444°·5
Sulphur dioxide	− 10°·0	Cadmium	+756°
Aniline	+184°·1	Zinc	+916°
Naphthalene	+218°·0		

Alphabetical Index of Symbols

A, B, C, Empirical constants in formulae; section 14.
b, Minimum volume or co-volume of vapour, equation (13).
C, Concentration of solution, gm. mols. per c.c.
c, Coaggregation-volume of vapour, equation (13).
D, d, Density of liquid and vapour.
E, Intrinsic energy of vapour.
g, Acceleration of gravity.
H, Total heat of vapour.
h, Heat of the liquid; height of capillary ascent.
L, Latent heat of vaporization.
M, Modulus of logarithms.
m, Molecular weight.
n, Index of θ in expression for c, equation (13).
P, Osmotic or capillary pressure.
p, Pressure of vapour.
Q, Cooling effects in adiathermal expansion.
R, Constant in gas equation, $pv=R\theta$.
r, Radius of curvature, formula (1).
S, Specific heat of vapour at constant pressure.
s, Specific heat of liquid, equation (23).
Specific heat of vapour at constant volume; section 8.
T, Surface tension of liquid.
t, Temperature Centigrade.
V, Ideal volume of vapour, equation (13).
Specific volume of solid or liquid, equation (5).
v, Specific volume of vapour or steam.
w, Specific volume of water or liquid.
θ, Temperature on thermodynamic scale.
ϕ, Entropy of vapour or liquid. (H. L. C.)

[1] Complete tables of the properties of steam have been worked out on the basis of Callendar's formulae by Professor Dr R. Mollier of Dresden, *Neue Tabellen und Diagramme für Wasserdampf*, published by J. Springer (Berlin, 1906).

VAQUERO, a Spanish word meaning a cowherd or herdsman, and so particularly used in Mexico and Spanish America for the whole class of men employed on the large cattle-ranches or *vaquerias*. The word, like the corresponding Fr. *vacher*, cowherd, comes from the Med. Lat. *vaccarius* (*vacca*, cow).

VAR, a department in S.E. France. It was formed in 1790 of a part of Lower Provence, but in 1860 it was reduced by the transfer of the district of Grasse to the newly formed department of the Alpes Maritimes, which is the reason why the Var does not now flow in the department to which it gives its name. It is bounded N. by the department of the Basses Alpes (the Verdon river forming the boundary), E. by that of the Alpes Maritimes (the Siagne stream forming the limit), S. by the Mediterranean, and W. by the department of the Bouches du Rhône. Its area is 2266 sq. m., its greatest length is about 62 m., and its greatest breadth about 56 m.

The surface of the department is very hilly, the highest point being the Signal des Chens (5620 ft.) at its north-east corner. These calcareous hills are much fissured and very dry on the highest plateaux, but are rich in springs, which is the cause of very beautiful verdure in the valleys. To the W. is the chain (3786 ft.) of the Ste Baume, wherein is the celebrated grotto (now a frequented pilgrimage place) wherein St Mary Magdalene is said to have taken refuge. This chain is connected with the hills (2329 ft.) above Toulon. The thickly wooded Montagnes des Maures (2556 ft.), which extend above the coast from Hyères to near Fréjus are separated from the Ste Baume chain by the Gapeau stream and from that of the Estérel by the Argens river: the Maures chain, with the Argens valley, forms a sort of geological island in Provence, being composed of granite, gneiss and schists. To the north of the Argens valley and in the north-eastern portion of the department rises the Estérel chain, the highest summit of which (the Mont Vinaigre) attains 2021 ft.: this chain is mainly composed of igneous rocks, with some schists and porphyry. The principal river in the department is the Argens, which traverses it from W. to E., and falls into the sea near Fréjus after a course of about 68 m. Its chief tributary is the Nartuby, on which stands Draguignan, the chief town, while other streams are the Arc, the Huveaune and the Gapeau. The extreme north-western extremity of the department borders for 2½ m. the Durance, which separates it from the department of Vaucluse. The coast line, which is one of the most picturesque and varied in France, runs first W. to E., from the Gulf of La Ciotat to Cape Camarat, and then S.W. to N.E., from the Gulf of St Tropez to that of La Napoule. The shore is dotted (from W. to E.) successively by the sand-covered remains of the Phocaean city of Tauroentum; the little ports of Bandol and St Nazaire; the peninsula of Cape Sicié (on which rises the chapel of Notre Dame de la Garde, and a famous lighthouse, 1178 ft.) with its eastward projection Cape Cépet (338 ft.), bristling with fortifications to protect the great harbour of Toulon, to the north-east; the roads of Toulon; those of Giens, on the site of the Gallo-Roman town of Pomponiana; the curious peninsula of Giens, formerly an island, but now attached to the mainland by two long spits of sand, between which lies the lagoon of Les Pesquiers, with its *salines*; the great anchorage of Hyères, shut off from the Mediterranean by the hilly and wooded islands of Porquerolles, Port Cros and Le Levant; the bold promontories of the Montagnes des Maures, that divide the coast into lovely bays; Cape Camarat (1066 ft.), with a lighthouse; the deep Gulf of St Tropez, with perhaps the best natural anchorage in all Provence; the Gulf of Fréjus, where, owing to the accumulated alluvial deposits at the mouth of the Argens, the Roman port of Forum Julii is now occupied by the inland town of Fréjus; the red porphyry headlands of the Estérel chain, with the roads of Agay between them; and Cape Roux (1486 ft.) looking towards Cannes, still farther N.E. The department is divided into three arrondissements (Draguignan, Brignoles and Toulon), 30 cantons and 148 communes. The climate is remarkably fine and mild on the coast, where there is complete shelter from the wind, St Raphaël (with Valescure above it) and Hyères being now much frequented winter resorts. The department now forms the bishopric of Fréjus (4th century), which is in the ecclesiastical province of Aix en Provence: in 1801 there was annexed to it the episcopal see of Toulon, founded in the 5th century, and in the ecclesiastical province of Arles. There are in the department 135 m. of broad gauge railways, and 148½ m. of narrow gauge lines. The principal towns are Toulon, La Seyne, Hyères, Draguignan, its political capital, Brignoles and Fréjus. There are a number of mines (chiefly iron and coal) in the department, and salt is extracted from the marshes near Hyères, while there are manufactories of pottery and extensive vineyards. La Seyne is the principal centre of industrial activity. Cut flowers are largely exported from Hyères. In 1901 the population of the department was 326,384. (W. A. B. C.)

VARALLO SESIA, a town of Piedmont, Italy, in the province of Novara, from which it is 34 m. N.N.W. by rail, situated in the valley of the Sesia, 1480 ft. above sea-level. Pop. (1901) 3330 (town); 4265 (commune). The churches of S Gaudenzio, S Maria delle Grazie and S Maria di Loreto, all contain works by Gaudenzio Ferrari (1471–1546), who was born in the neighbouring Val Duggia, while the Sacro Monte, a place of pilgrimage rising above the town (1995 ft.), is approached by a path leading past forty-five chapels containing groups of life-size painted terra-cotta figures representing scenes from sacred history, with backgrounds in fresco (by Ferrari and others), to the pilgrimage church built by Pellegrino Tibaldi after 1578. In the works mentioned, as Burckhardt remarks, Ferrari's whole development may be traced.

VARCHI, BENEDETTO (1502–1565), Florentine historian. He fought in the defence of Florence during the siege by the Mediceans and imperialists in 1530, and was exiled after the surrender of the city. In 1536 he took part in Piero Strozzi's unsuccessful expedition against Medicean rule, but seven years later he was called back to Florence by Cosimo I., who gave him a pension and commissioned him to write a history of the city; the work covers the period from 1527 to 1538. Varchi also wrote a number of plays, poems, dialogues and translations from the classics. His history, in sixteen books, was first published in Florence in 1721.

VARDANES, the name of two Parthian kings.

VARDANES I., succeeded Artabanus II., probably his father, in A.D. 40 (Joseph. *Ant.* xx. 3, 4), but had continually to fight against his rival Gotarzes (*q.v.*). The coins show that he was in full possession of the throne from 42 to 45. In 43 he forced Seleucia on the Tigris to submit to the Parthians again after a rebellion of seven years (Tac. *Ann.* xi. 9). Ctesiphon, the residence of the kings on the left bank of the Tigris, opposite to Seleucia, naturally profited by this war; and Vardanes is therefore called founder of Ctesiphon by Ammianus Marc. xxiii. 6. 23. He also prepared for a war against Rome, with the aim of reconquering Armenia (cf. Joseph, *Ant.* xx. 3, 4), but did not dare to face the Roman legions (Tac. *Ann.* xi. 10). In a new war with Gotarzes he gained a great success against the eastern nomads. He is praised by Tacitus as a young and highly gifted ruler of great energy (cf. Philostratus, *Vita Apollon. Tyan.* i. 21. 28), but lacking in humanity. In the summer of 45 he was assassinated while hunting, and Gotarzes became king again.

VARDANES II. rebelled against his father Vologaeses I. in A.D. 54 (Tac. *Ann.* xiii. 7). We know nothing more about him and it is not certain whether the coins of a young beardless king, which are generally attributed to him, really belong to him (Wroth, *Catalogue of the Coins of Parthia*, p. L. ff.). (ED. M.)

VARENIUS, BERNHARDUS [BERNHARD VAREN] (1622–1650), German geographer, was born at Hitzacker on the Elbe, in the Lüneburg district of Hanover. His early years (from 1627) were spent at Uelzen, where his father was court preacher to the duke of Brunswick. Varenius studied at the gymnasium of Hamburg (1640–42), and at Königsberg (1643–45) and Leiden (1645–49) universities, where he devoted himself to mathematics and medicine, taking his medical degree at Leiden in 1649. He then settled at Amsterdam, intending to practise medicine. But the recent discoveries of Tasman, Schouten and other Dutch navigators, and his friendship for Blaeu and other geographers, attracted Varenius to geography. He died in 1650, aged only twenty-eight, a victim to the privations and miseries of a poor scholar's life.

In 1649 he published, through L. Elzevir of Amsterdam, his *Descriptio Regni Japoniae*, an excellent compilation. In this was included a translation into Latin of part of Jodocus Schouten's account of Siam (*Appendix de religione Siamensium, ex Descriptione Belgica Iodoci Schoutenii*), and chapters on the religions of various peoples. Next year (1650) appeared, also through Elzevir, the work by which he is best known, his *Geographia Generalis*, in which he endeavoured to lay down the general principles of the subject on a wide scientific basis, according to the knowledge of his day. The work is divided into—(1) absolute geography, (2) relative geography and (3) comparative geography. The first investigates mathematical facts relating to the earth as a whole, its figure, dimensions, motions, their measurement, &c. The second part considers the earth as affected by the sun and stars, climates, seasons, the difference of apparent time at different places, variations in the length of the day, &c. The third part treats briefly of the actual divisions of the surface of the earth, their relative positions, globe and map-construction, longitude, navigation, &c.

Varenius, with the materials at his command, dealt with the subject in a truly philosophic spirit; and his work long held its position as the best treatise in existence on scientific and comparative geography. The work went through many editions. Sir Isaac Newton introduced several important improvements into the Cambridge edition of 1672; in 1715 Dr Jurin issued another Cambridge edition with a valuable appendix; in 1733 the whole work was translated into English by Dugdale; and in 1736 Dugdale's second edition was revised by Shaw. In 1716 an Italian edition appeared at Naples; in 1750 a Dutch translation followed; and in 1755 a French version, from Shaw's edition, came out at Paris. Among later geographers d'Anville and A. von Humboldt especially drew attention to Varen's genius and services to science.

See Breusing, "Lebensnachrichten von Bernhard Varenius" (*Geogr. Mittheil.*, 1880); H. Blink's paper on Varenius in *Tijdschr. van het Nederl. Aandrijksk. Genotschap* (1887), ser. ii. pt. 3; and F. Ratzel's article "Bernhard Varenius," in *Allgemeine Deutsche Biographie*, vol. xxxix. (Leipzig, 1895).

VARESE, a town of Lombardy, Italy, in the province of Como, 18 m. by rail W. of that town, and 37 m. N.W. of Milan, 1253 ft. above sea-level. Pop. (1901) 7692 (town); 17,666 (commune). It is a well-to-do place, beautifully situated near the Lake of Varese, and for this reason a favourite summer and autumn resort of the Milanese, who have numerous country houses in the vicinity. Among them the Villa Litta and the Villa Ponte may be specially mentioned. The principal church is that of S. Victor (rebuilt 1580–1615 and 1795), to which is attached an ancient baptistery (dating from the 9th century but rebuilt in the 13th). The fine campanile of the church is 246 ft. high. There is an archaeological museum with prehistoric antiquities from the lake-dwellings on an island in the Lake of Varese. To the N.W. (a journey of 2½ hours) is the pilgrimage church of the Madonna del Monte (2885 ft.), approached by a path which passes fourteen chapels adorned with 17th-century frescoes and groups in stucco illustrating the mysteries of the rosary. Varese is the seat of active silk-spinning, tanning, paper-making and the manufacture of organs and vehicles. Excellent wine is made. Varese is a junction for Porto Ceresio and Laveno.

VARIA (mod. Vicovaro), an ancient village of Latium, Italy, in the valley of the Anio, on its right bank, and on the Via Valeria, 8 m. N.E. of Tibur (Tivoli). It was probably an independent town and not within the territory of Tibur, and Horace speaks of it as Sabine. Some remains of its walls, in rectangular blocks of travertine, still exist. One mile to the east is a picturesque gorge of the Anio, in which may be seen remains of the ancient aqueducts which supplied Rome, consisting partly of rock-cut channels and partly of ruined bridges: above it is the monastery of S Cosimato. Close to this point begins the valley of the Digentia (mod. Licenza) in which Horace's Sabine farm was situated. On the hill at the east of the entrance is the village of Cantalupo or Bardella, which has now assumed the name of Mandela, being identified thus (correctly) with Horace's "rugosus frigore pagus" (*Epist.* i. 18, 104). An inscription of the Christian period, found at S Cosimato, speaks of the Massa Mandelana (*Corp. Inscr. Lat.* xiv. 3482). About 3 m. up the valley, close to the road on the west (right) bank of the stream, are traces of a Roman dwelling-house in *opus reticulatum* with remains of two mosaic pavements; this is generally identified with the villa of Horace, and probably corresponds fairly closely with its site. That the Fons Bandusiae was near the Sabine farm is not a necessary inference from *Od.* iii. 13, in which alone it is mentioned; though the scholiasts state it; indeed a fountain of this name near Venusia is mentioned in a bull of 1103. On the other hand, that there was an abundant fountain near the Sabine farm is clear from *Epist.* i. 16. 12, and *Sat.* ii. 6. 2. It is generally identified with the Fonte dei Ratini, but the spring of Vigna la Corte, a little farther north, is still more plentiful. Some have supposed that the site of the villa was higher up the hillside, above Rocca Giovane. For Horace speaks of having written *Epist.* i. 10 "post fanum putre Vacunae," and an inscription recording a temple of Victoria restored by Vespasian was copied at Rocca Giovane in the 16th century (*Corp. Inscr. Lat.* xiv. 3485). The identification of Victoria with the Sabine goddess Vacuna is not, however, absolutely certain: and there is here, as elsewhere in Roman literature, a play on the connexion of the name with *vacare*, "to take a holiday." In any case, the site of the Sabine farm can be approximately, if not exactly, fixed as in the neighbourhood of Rocca Giovane.

VARIATION AND SELECTION, in biology. Since the publication in 1859 of Charles Darwin's *Origin of Species*, the theory of evolution of animals and plants (see EVOLUTION) has rested on a linking of the conceptions of variation and selection. Living organisms vary, that is to say, no two individuals are exactly alike; the death-rate and the multiplication-rate are to a certain extent selective, that is to say, on the average, in the long run, they favour certain variations and oppress other variations. Co-operation of the two factors appears to supply a causal theory of the occurrence of evolution; the suggestion of their co-operation and the comparison of the possible results with the actual achievements of breeders in producing varieties were the features of Charles Darwin's theoretical work which made it a new beginning in the science of biology, and which reduced to insignificance all earlier work on the theory of evolution. P. Geddes, J. H. Stirling, E. Clodd and H. F. Osborn have made careful studies of pre-Darwinian writers on evolution, but the results of their inquiries only serve to show the greatness of the departure made by Darwin.

Several of the ancients had a vague belief in continuity between the inorganic and the organic and in the modifying or variation-producing effects of the environment. Medieval writers contain nothing of interest on the subject, and the speculations of the earliest of the modern evolutionists, such as C. Bonnet, were too vague to be of value. G. L. L. Buffon, in a cautious, tentative fashion, suggested rather than stated the mutability of species and the influence of the forces of nature in moulding organisms. Immanuel Kant, in his *Theory of the Heavens* (1755), foreshadowed a theory of the development of unformed matter into the highest types of animals and plants, and suggested that the gradations of structure revealed by comparative anatomy pointed to the existence of blood relationship of all organisms, due to derivation from a common ancestor. He appeared to believe, however, that the successive variations and modifications had arisen in response to mechanical laws of the organisms themselves rather than to the influence of their surroundings. J. G. von Herder suggested that increase by multiplication with the consequent struggle for existence had played a large part in the organic world, but his theme remained vague and undeveloped. Erasmus Darwin, the grandfather of Charles Darwin, set forth in *Zoonomia* a much more definite theory of the relation of variation to evolution, and the following passage, cited by Clodd, clearly expresses it:—

"When we revolve in our minds the metamorphoses of animals, as from the tadpole to the frog; secondly, the changes produced by artificial cultivation, as in the breeds of horses, dogs and sheep; thirdly, the changes produced by conditions of climate and season, as in the sheep of warm climates being covered with hair instead of wool, and the hares and partridges of northern climates becoming white in winter; when, further, we observe the changes of structure produced by habit, as shewn especially by men of different occupations; or the changes produced by artificial mutilation and prenatal influences, as in the crossing of species and production of monsters; fourth, when we observe the essential unity of plan in all warm-blooded animals—we are led to conclude that they have been alike produced from a single living filament."

G. R. Treviranus, in the beginning of the 19th century, laid stress on the indefiniteness of variation, but assumed that some of it was adaptive response to the environment, and some due to sexual crossing. J. B. P. Lamarck was the first author to work out a connected theory of descent and to suggest that the relationships of organic forms were due to actual affinities. He believed that life was an expanding, growing force, and that animals responded to the environment by developing new wants, seeking to satisfy these by new movements and thus by their own striving producing new organs which were transmitted to their descendants. Variation was in fact a purposive response.

In 1813 W. C. Wells definitely propounded the theory of natural selection, but applied it only to certain human characters. In 1831 Patrick Matthew, in the appendix to a book on naval timber and arboriculture, laid stress on the extreme fecundity of nature "who has in all the varieties of her offspring a prolific power much beyond (in many cases a thousandfold) what is necessary to fill up the vacancies caused by senile decay. As the field of existence is limited and pre-occupied, it is only the hardier, more robust, better-suited-to-circumstance individuals, who are able to struggle forward to maturity, these inhabiting only the situations to which they have superior adaptation and greater power of occupancy than any other kind; the weaker and less circumstance-suited being prematurely destroyed. This principle is in constant action; it regulates the colour, the figure, the capacities and instincts; those individuals in each species whose colour and covering are best suited to concealment or protection from enemies, or defence from inclemencies or vicissitudes of climate, whose figure is best accommodated to health, strength, defence and support; whose capacities and instincts can best regulate the physical energies to self-advantage according to circumstances—in such immense waste of primary and youthful life those only come to maturity from the strict ordeal by which nature tests their adaptation to her standard of perfection and fitness to continue their kind by reproduction." G. St Hilaire and afterwards his son Isodore regarded variation as not indefinite but directly evoked by the demands of the environment. L. von Buch laid stress on geographical isolation as the cause of production of varieties, the different conditions of the environment and the segregated interbreeding gradually producing local races. K. E. von Baer and M. J. Schleiden regarded variation and the production of new or improved structures as an unfolding of possibilities latent in the stock. Robert Chambers, in the once famous *Vestiges of Creation*, interested and shocked his contemporaries by his denial of the fixity of species and his insistence on creation by progressive evolution, but had no better theory of the cause of variation than to suppose that organisms—"from the simplest and oldest to the highest and most recent" were possessed of "an inherent impulse, imparted by the Almighty both to advance them from the several grades and modify their structure as circumstances required." In 1852 C. Naudin compared the origin of species in nature with that of varieties under cultivation. Herbert Spencer from 1852 onwards maintained the principle of evolution and laid special stress on the moulding forces of the environment which called into being primarily new functions and secondarily new structures.

Although the pre-Darwinian writers amongst them invoked nearly every principle that Darwin or his successors have suggested, they failed to carry conviction with regard to evolution, and they neither propounded a coherent philosophy of variation nor suggested a mechanism by which variations that appeared might give rise to new species. The anticipations of Darwin were little more than formal and verbal. As T. H. Huxley pointed out in his essay on the reception of the *Origin of Species* in the second volume of Darwin's *Life and Letters*, "The suggestion that new species may result from the selective action of external conditions upon the variations from their specific type which individuals present—and which we call 'spontaneous' because we are ignorant of their causation—is as wholly unknown to the historian of scientific ideas as it was to biological specialists before 1858. But that suggestion is the central idea of the *Origin of Species*, and contains the quintessence of Darwinism."

C. Darwin opened his argument by consideration of plants and animals under domestication. He pointed to the efflorescence of new forms that had come into existence under the protection of man. A multitude of varieties of cultivated plants and domesticated animals existed, and these differed amongst themselves and from their nearest wild allies to an extent that, but for the fact of their domestication, would entitle them to the systematic rank of species. Some of these changes he supposed to have been the result of new conditions, including abundance of food and protection from enemies, but most he attributed to the accumulated results of selective breeding. No doubt such domesticated species might revert, and it has been shown that many do revert when restored to wild conditions, but such reversion is natural if we reflect that the domestic varieties are under the guardianship of man and have been selected according to his whim and advantage. Comparing domesticated varieties with species and varieties in nature, Darwin showed that the distinction between varieties and species was chiefly a matter of opinion, and that the discovery of new linking forms often degraded species to varieties. Species, in fact, were not fixed categories, but halting-places, often extremely difficult to choose, for the surveying mind of the systematist. He considered that a struggle for existence was the inevitable result of the operation of the principle of Malthus in the animal and vegetable worlds. The struggle would be most acute between individuals and varieties of the same species, with the result that "any being, if it vary however slightly, in any manner profitable to itself, under the complex and somewhat varying conditions of life, will have a better chance of surviving, and thus be naturally selected." Under natural selection the less well-adapted forms of life would on the average have a heavier death-rate and a lower multiplication-rate. He did not suggest that every variation and every character must have a "selection value," although he pointed out that, because of our ignorance of animal physiology, it was extremely rash to set down any characters as valueless to their owners. It is even more important to notice that he did not suggest that every individual with a favourable variation must be selected, or that the selected or favoured animals were better or higher, but merely that they were more adapted to their surroundings.

With regard to variation, Darwin was urgent in stating his opinion that the laws of variation were not understood and that the phrase "chance" variation was a wholly incorrect expression. He thought it probable that circumstances affecting the reproductive system of the parents had much influence in producing a plastic condition of the progeny. He doubted, but did not exclude, the importance of the direct effect of differences of climate and food and of increased use and disuse, except so far as the individual was concerned, but his opinion as to these Lamarckian factors changed from time to time. He laid much stress on the unity of the organism in every stage of its existence, with the resulting correlation of variations, so that the favouring of one particular variation entailed modifications of correlated structures. He recognized the existence of the large variations, but he believed these to be of little value in evolution, and he attached preponderating importance to relatively minute indeterminate variations. On the other hand, he was far from advocating the view that has been pithily expressed as the "selection of the fit from the fortuitous"; he recognized that variations, although perhaps suggested or excited by the environment, were determined by internal causes. He showed how different varieties in a species, or species in a genus, tended to display parallel variation, clearly indicating that the range and direction of variation were limited or determined by the nature of the organism.

Alfred Russel Wallace, the co-discoverer of the Darwinian principles, had sent to Darwin early in 1858 an outline of a theory of the origin of species. Darwin found that it was, in all essential respects, identical with his own theory at the exposition of which he had been working for many years. With an unselfish generosity which must always shine in the history of science, and indeed of the human race, Darwin proposed at once to communicate his correspondent's essay to the Linnaean Society of London, but was persuaded by his friends to send with it an outline of his own views. Accordingly, on the same evening, in July 1858, both communications were made to the Linnaean Society. When Wallace found how much more fully Darwin was equipped for expounding the new views, he exhibited an unselfish modesty that fully repaid Darwin's generosity, henceforth described himself as a follower of Darwin, entitled his most important publication on the theory of evolution *Darwinism*, and did not issue it until 1889, long after the world had given full credit to Darwin. In most respects his ideas were closely parallel with those of Darwin. He believed that species had been formed by means of natural selection. He insisted that the great powers of increase of all organisms led to a tremendous struggle for existence, and that variability extended to every part and organ of every organism; that the variability was large in amount in proportion to the size of the part affected, and occurred in a considerable proportion of the individuals of those large and dominant species which might be supposed to be breaking up into new species. He pointed to the changes wrought on domesticated organisms by the artificial selection of similar variations, and drew the inference that there must be parallel occurrences under wild nature. In the sphere of nature, with its vast numbers and constant pressure, not every more favoured individual would survive, nor every surviving individual be the more favoured, but throughout the changes and chances there would be a constant and important bias in favour of the individuals more fitted to their conditions. Wallace, however, brought into his scheme a factor excluded by Darwin. He believed that behind the natural world lay a spiritual world, irruptions from which had disturbed the natural sequence of causation, certainly in the production of the higher emotional and mental qualities of man, probably in the appearance of self-consciousness, and possibly in the first origin of life.

It is to be remembered that the origin of species by the modification of pre-existing species,—in fact, the doctrine of organic evolution,—although first made credible by Darwin and Wallace, does not depend upon their theory of the relation of natural selection to variation. The theory of evolution is supported by a great range of evidence, much of which was first collected by Darwin, and which has been enormously increased by subsequent workers excited by his genius. Such evidence relates to the facts of classification, structure, development, and geographical and geological distribution. It now remains to examine in closer detail the further knowledge that has been gained with regard to variation and the bearing of that on the Darwinian position.

Magnitude of Variation.—Darwin was well aware that variation ranged from differences so minute as to become apparent only on careful measurement to those large departures from the normal which may be called abnormalities, malformations or monstrosities. He was of the opinion that the summation of minute differences had played a preponderating if not exclusive part in the formation of species. Wallace, whilst insisting that the range of observed and measured variation was much larger in proportion to the size of the organisms or parts of organism affected than was generally believed, leaned to the Darwinian view in excluding from the normal factors in the origin of species variations of the extremer ranges of magnitude. Later writers, and in particular W. Bateson and H. de Vries, have urged that as species are discontinuous—that is to say, marked off by structural differences of considerable magnitude—it is more probable that they have arisen from similarly discontinuous variations. De Vries gave the name "mutations" to such considerable variations (it is to be noted that a further concept, that of the mode of origin, has been added to the word mutation, and that the conception of relative size is being removed from it), and Bateson, de Vries and other writers have added many striking cases to those recorded by Darwin. It is doubtful, however, if there is any philosophical basis for distinguishing between variations merely by their magnitude. Differences which at their first appearance are very minute may result in the kind of variations which certainly would be classed as discontinuous. When the cells of the *morula* stage of an embryo are shaken asunder, each, instead of forming the appropriate part of a single organism, may form a complete new organism. And similarly in the development of a complicated organism, the suppression or doubling of a single cell or group of cells may bring about striking differences in the symmetry of the adult, or the reduction or increase in the number of metameric organs. A slight change in the structure or activity of a gland, by altering the internal secretion, may produce widespread alterations even in an adult organism; and we have good reason to suppose that, if compatible with viability, such minute changes would have even a greater ultimate effect if they occurred in an embryo. Even amongst the extreme advocates of the theory of mutations, the importance of magnitude is being discounted by their suggestion that some of the minute variations which have hitherto been regarded by them as insignificant "fluctuating variations" may be significant mutations. This in effect is to say that not magnitude but something else has to be sought for if we are to pick out amongst observed variations those which may be the material for the differentiation of species. So far as magnitude is concerned, the attack on the Darwinian position has failed, and it is agreed that species may be discontinuous and none the less have been produced from minute variations.

Causes of Variation.—Darwin was careful to insist that we did not know the laws of variation, and that when variation was attributed to "chance" no more should be read into the statement than an expression of our ignorance of the causation. It cannot now be doubted that a very large amount of observed variation, and especially of the indefinite variation which is sometimes spoken of as fluctuating variation, and which is usually distributed indefinitely round a mean, is directly associated with or induced by the environment. On various grounds attempts have been made to exclude such variation from the material for the making of species. The variations which de Vries has called mutations, and which were at first associated by Bateson with what he called discontinuous variations as the exclusive source of new species, are now supposed by de Vries to be distinguished from fluctuating variations by their mode of origin. Such mutations are not the product of the environment, but are an outcrop of the constitution of the germinal material of the varying organism, the result either of causes as yet undetected, or of the premutations and eliminations suggested by the work of Mendel (see MENDELISM). These attempts to reject environmental variation rest on several grounds. In the first place the variations in question are "acquired characters." When Darwin and Wallace framed their theories it was practically assumed that acquired characters were inherited, and the continuous slow action of the environment, moulding each generation to a slight extent in the same direction, was readily accepted by a generation inspired by Sir C. Lyell's doctrine of uniformitarianism in geological change, as a potent force. A. Weismann, however, from theoretical considerations and from analysis of supposed cases has at the least thrown doubt on the transmission of acquired characters. And so the newer school discard acquired characters and all the Lamarckian factors and leave the board clear for "mutations." Analysis of any acquired character, however, shows that there are two factors involved. The organism is not a passive medium; the amount and nature of the response it makes to the action of environment depends on its own qualities, and these qualities, on any theory of inheritance, pass from generation to generation. Successful organisms, or well-adapted organisms, are those that have responded to the environment, whether by large or small variations, in suitable fashion. It is the character as acquired that affords the opportunity for selection, but the quality of responding to the environment so as to produce that character is transmitted. The conceptions of Weismann afford no ground for rejecting fluctuating variations from the materials for the production of species.

In the second place, it has been urged, particularly by de Vries, that experiment and observation have shown that the possible range of fluctuating variation is strictly limited. Breeders, he says, who try to build up qualities by the selection of the fluctuating variations that occur soon find that they reach a maximum beyond which their efforts fail, unless they turn to the more rarely occurring but heritable mutations. Something will be said later in this article as to the limitation of variation; here it is necessary only to say that de Vries is introducing no new idea. It is well known that some races and some organs in plants and animals are extremely variable, and that others are much less variable, and further, that whilst some of these differences may be due to intrinsic causes, others can be modified by experiment. As Sir W. T. Thiselton-Dyer has pointed out, what is called "specific stability" is a familiar obstacle to the producer of novelties, but one which he frequently succeeds in breaking down by cultural and other methods. In a survey of the palaeontological history of plants and animals, it is plain that extreme stability and extreme mutability both have occurred, sometimes having persisted for untold ages, sometimes having succeeded one another for varying periods. As yet no solid reason has been alleged for excluding fluctuating variations, on account of their limitation, from the materials for specific change. J. Cossar Ewart and H. M. Vernon have adduced experimental evidence as to the induction of variation by such causes as difference in the ages of the parents, in the maturity or freshness of the conjugating germ cells, and in the condition of nutrition for the embryos. Such cases show in the plainest way the co-operation of external or environmental and internal or constitutional factors.

With our present knowledge it is impossible to discriminate between variation that may or that may not be the material for the differentiation of species by scrutinizing either magnitude or probable causation. It is equally impossible to draw an exact line between variation induced by the environment and variation that may be termed intrinsic. Extrinsic and intrinsic factors are involved in every case, although there is a range from instances in which the external factor appears to be extreme to instances where the intrinsic factor is dominant. Even the results of mutilation involve an intrinsic factor, for they range, according to the organ and organism affected, from complete regeneration to the most imperfect healing. In the effects of exercise, of physiological activity and the gross results of such external agencies as food, temperature, climate, light, pressure and so forth the intrinsic factor appears to become more important. The interplay of extrinsic and intrinsic factors also differs with the age of the organism affected: the more nearly adult it may be, the more direct appears to be the influence of the environment; the more nearly embryonic the organism may be, the less direct is the result of a force impressed from without. The old organism is more stable and responds in obvious ways to direct assaults from without; the young organism is at once less stable and more profoundly modified by environmental change, replying in terms less easy to predict from knowledge of the nature and amount of the impinging agency. And finally, there are a series of variations, amongst which no doubt are the mutations of de Vries and the disintegrations and recombinations of the unit factors with which Mendel and his followers have worked, in which the external or environmental factor is most remote from the actual result.

Correlated Variation.—Every organism is an individual, its different parts, organs and functions being associated in a degree of intimacy that varies, but that corresponds roughly with the integration of the individual and its place in the ascending scales of animal or vegetable life. One aspect of organic individuality is the correlation of variations, the fact that when one part varies, other parts vary more or less simultaneously. So far, our knowledge of correlation is almost entirely empirical, and the arrangement of the observed facts cannot be brought into exact harmony with our guesses at their causation.

Much correlation is the inevitable result of organic structure. The various parts of a living organism affect each other in adult life and during growth. If, for instance, the testes fail to develop normally, the secretion which they discharge into the blood is abnormal in character and amount, with the result that the characters of the remotest parts of the body are more or less profoundly affected. It is now known that similar internal secretions, or hormones, pass into the blood trom every organ and tissue, so reaching and affecting every part of the body. If we reflect on the multitude and complexity of such actions and reactions in operation from the youngest stages to the end of the life of each individual, we cannot be surprised at any correlation. Change in the size of any part or organ, however it may have been produced, must bring with it many others changes, directly or indirectly. A difference in calibre, elasticity or branching of a blood vessel, the smallest variation in a nerve or group of vessel-cells, any anatomical or physiological divergence, is reflected throughout the organism. Much of the character of organisms is due to various symmetries, radial, bilateral, metameric and so forth, and these symmetries arise, partly at least, from the mode of growth by cell division and the marshalling of groups of cells to the places where they are destined to proliferate. Here, again, a variation in the order, nature and number of the divisions, in itself simple, may result in symmetrical or correlated changes in all the progeny of the affected embryonic part.

Every new individual starts life (see REPRODUCTION) as a mass of germinal material derived from one or from two parents, but with a coherent individuality of its own. This individuality is the result of the particular selection of qualities it receives from its parents, a selection that obviously differs in different cases, as, save in the case of "identical twins," which are supposed to be the product of a single fertilized ovum, no individual pair of brothers, or pair consisting of brother and sister, are alike. We are still ignorant of the causes that determine the associated selection of inherited qualities that go to the making of any individual. Those who have followed up the work of Mendel believe that the qualities of the new individual are a precise selection from and reconstruction of the parental qualities, and that were complete analysis possible, the characters of the new individual could be predicted with chemical accuracy. On other views of inheritance, there would be required for prediction knowledge not only of the immediate parents but of the whole line of ancestry, with the result that prediction could reach only some degree of probability for any single individual and be accurate only for the average of a sufficient number of individuals. But whatever be the theory of the mode of inheritance, or the mechanism by which the germinal plasm of an individual is made up, it is plain that there is correlation between the various qualities of an individual due to the mode of origin of its germ plasm as a selected individual portion of the parental germ plasm.

Observed cases of correlation cover almost every kind of anatomical and physiological fact, and range from simple cases such as the relation between height of body and length of face to such an unexpected nexus as that between fertility and height in mothers of daughters. The statistical investigation of correlations forms a new branch of biological inquiry, generally termed "Biometrics," inaugurated by F. Galton and carried on by Karl Pearson and the late W. F. R. Weldon.

We quote from the article "Variation and Selection," in the tenth edition of this *Encyclopaedia*, an exposition of the biometric method by Weldon:—

The characters of individual animals or plants depend upon so many complex conditions, most of which are generally unknown to us, that the statements we can make concerning them are of a peculiar kind. We cannot predict with any exactness the characters of a single unborn individual; but if we consider a large number of unborn individuals, we can predict with considerable accuracy the percentage of individuals which will have the mean character proper to their generation, or will differ from that mean character within any assigned limits. So long as we confine our attention to one or two individuals, we fail to detect any order in the occurrence of variations; but when we examine large numbers we find that it is possible to arrange them in an orderly series, which can be easily and simply described. The series into which we can arrange the results of observing phenomena of complex causation, whether exhibited by living organisms or not, have certain properties in common, which are dealt with by the theory of chance. Many of the properties of such series, and the methods of describing them, are dealt with elsewhere (see PROBABILITY: *Law of Error*); and the frequency with which the mean value or any deviation from the mean value of a character occurs in a race of animals or of plants may probably always be expressed in terms of one or other of the series there described. The theory of chance was applied to the study of human variation by Quetelet; but the most important applications of this theory to biological problems are due in the first instance to Francis Galton, who used the theory of *correlation* in describing the relation between the deviation of one character in an animal body from the mean proper to its race and that of a second character in the same body (correlation as commonly understood), or between deviation of a parent from the mean of its generation and deviation of offspring from the mean of the following generation (inheritance). The conceptions indicated by Galton have been extended and added to by Karl Pearson, who has also developed the theory of chance so as to provide a means of describing many series of complex results in a simpler and more accurate way than was hitherto possible.

The conception of a race of animals or of plants as a group of individuals capable of being arranged in an orderly series with respect to the condition of a particular character enables us to define the "type" of that character proper to the race. Table I. shows the number of female swine which had a given number of "Müller's glands" on the right fore leg, in a sample of 2000 swine observed by Davenport in Chicago. If we take the whole number of glands in the series, and divide this by the whole number of swine, we obtain the *mean* number of glands per swine. For many purposes this is the most convenient "type" of the series. Two other ways of determining a "type" will be obvious by reference to the diagram, fig. 1, in which the observed results are recorded by the thick continuous line, and the form of Pearson's "generalized probability curve" best fitted to represent them by a dotted line. The ordinate of the dotted curve which contains its "centre of gravity" has, of course, for its abscissa the "mean" number of glands; the maximum ordinate of the curve is, however, at 2·98, or sensibly at 3 glands, showing what Pearson has called the "modal" number of glands, or the number occurring most frequently. The ordinate which divides the area of the dotted curve into two equal areas is the *median* of Galton: it lies in this case nearly at 3·38 glands. The best simple measure of the frequency of deviations from the mean character is the "standard deviation" or "error of mean square" of the system (see article PROBABILITY), in this case equal to 1·68 glands.

TABLE I.

Number of Glands.	Number of Swine.	Number of Glands.	Number of Swine.
0	15	6	134
1	209	7	72
2	365	8	22
3	482	9	8
4	414	10	2
5	277		

In cases of nearly symmetrical distribution about the mean, the three "types," the mean, the median and the mode, may sensibly coincide. For example, in Powis's table of the frequency of statures in male Australian criminals between 40 and 50 years of age (*Biometrika*, vol. i. part 1, p. 41), the mean stature is 66·91 in., the modal 66·96 in., the median lying between the

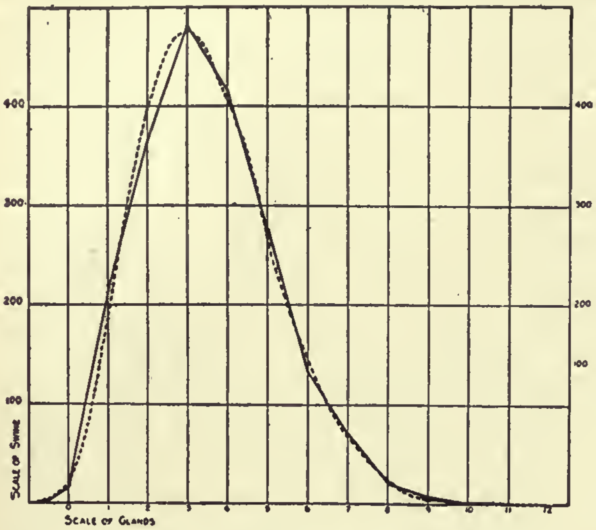

Fig. 1.

two. In other cases the difference between the three may be considerable. As an example of extreme asymmetry we may take de Vries's record of the frequency with which given numbers of petals occur in a certain race of buttercups. Pearson has shown (*Phil. Trans.*, A., 1893) that this frequency may be closely represented by the curve whose equation is

$$y=0\cdot211225x^{-0\cdot332}(7\cdot3253-x)^{3\cdot142}.$$

The curve, and the observations it represents, are drawn in fig. 2. The two are compared numerically in Table II. Here the mode is at 4·5 petals, the mean at 5·6 petals, the median lying of course between the two.

Table II.

Numbers of petals	5	6	7	8	9	10	11
Frequency observed	133	55	23	7	2	2	0
Frequency given by Pearson's curve	136·9	48·5	22·6	9·6	3·4	0·8	0·2

The distributions represented in figs. 1 and 2 may be taken as examples of three common forms of series into which the individuals of a race may be arranged with respect to a single character; a comparison of them will show how little can be learnt from a mere statement of racial type, without some knowledge of the way in which deviations from the type are distributed.

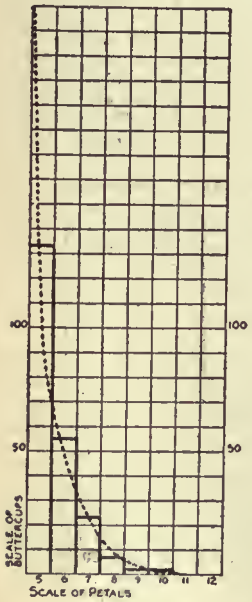

Fig. 2.

The variability of structures which are repeated in the body of the same individual (serial homologues) has been studied by Pearson and his pupils with important results. The simplest of such repeated elements are the cells of the tissues, more complex are cell-aggregates, from hairs, scales, teeth and the like, up to limbs or metameres in animals, or the leaves and their homologues in plants. Serially homologous structures, borne on the same body, are commonly differentiated into sets, the mean character of a set produced in one part of the body, or during one period of life, differing from the mean character of a set produced in a different region or at a different time. Such differentiation may be measured by determining the correlation between the position or the time of production and the character of the organs produced, the methods by which the correlation is measured being those described in the article Error, Law of. An excellent example of structures differentiated according to position is given by the appendages borne on the stem of an ordinary flowering plant—the one or two seed leaves; the stem leaves, which may or may not be differentiated into secondary sets; and the various floral organs borne at the apex of the stem or its lateral branches. The change which often occurs in the mean character and variability of the flowers produced at different periods of the flowering season by the same plant is an example of differentiation associated with time of production; as this kind of differentiation is less familiar than differentiation according to the region of production, it may be well to give an example. In a group of plants of *Aster prenanthoides*, examined by G. H. Shull (*American Naturalist*, xxxvi., 1902), the mean number of bracts, ray-florets and disc-florets, and the standard deviation of each, was determined on four different days, with the following result:—

Table III.

	Sept. 27.	Sept. 30.	Oct. 4.	Oct. 8.
Mean No. of bracts	47·41	44·34	43·83	41·92
Standard deviation	5·52	5·15	5·28	4·89
Mean No. of ray-florets	30·77	28·71	28·25	26·34
Standard deviation	3·99	3·57	3·50	3·01
Mean No. disc-florets	56·43	51·71	49·16	45·78
Standard deviation	3·99	4·99	4·88	4·78

Notwithstanding this differentiation, the mean character of a series of repeated organs is often constant through a considerable region of the body or a considerable period of time; and the standard deviation of an "array" of repeated parts, chosen from such an area, or within such limits of time, may be taken as a measure of the individual variability of the organism which produces them. If such an array of repeated organs be chosen from the proper region of the body, within proper limits of time, in each of a large series of individuals belonging to a race, and if all the arrays so chosen be added together, a series will be formed from which the *racial variability* can be determined. Thus a series of arrays of beech leaves, gathered, subject to the precautions indicated, from each of 100 beech trees in Buckinghamshire by Professor Pearson, gave 16·1 as the mean number of veins per leaf, the standard deviation of the veins in the series being 1·735. The number of leaves gathered from each tree was 26, and the frequency of leaves with any observed number of veins in the whole series of 2600 leaves was as follows:—

Table IV.

No. of veins	10	11	12	13	14	15	16	17	18	19	20	21	22
No. of leaves	1	7	34	110	318	479	595	516	307	181	36	15	1

The whole series contains 2600 leaves. If a leaf from this series be chosen at random, it is clearly more likely to have sixteen veins than to have any other assigned number; but if a first leaf chosen at random should prove to have some number of veins other than sixteen, a second leaf, chosen at random from the same series, is still more likely to have sixteen veins than to have any other assigned number. If, however, a series of leaves *from the same tree* be examined in pairs, the fact that one leaf from the tree is known to possess an abnormal number of veins makes it probable that the next leaf chosen from the same tree will also be abnormal—or, in other words, the fact that leaves are borne by the same tree establishes a correlation between them. Professor Pearson has measured this correlation. Taking each leaf of his series, with an assigned number of veins, he has determined the array of pairs of leaves which can be formed by pairing the chosen leaf with all others from its own tree in succession. The pairs so formed were collected in a table, from which the correlation between the first leaf and the second leaf of a pair, chosen from one tree, could be determined by the methods indicated in the article Probability. The mean and standard deviation of all first leaves or of all second leaves will clearly be the same as those already determined for the series of leaves; since every leaf in the series is used once as a first member and once as a second member of a pair. The coefficient of correlation is 0·5699, which indicates that the standard deviation of an array is equal to that of the leaves in general multiplied by $\sqrt{1-(0\cdot5699)^2}$; and performing this multiplication, we find 1·426 as the standard deviation of an array. The variability of an array of such a table—that is, of any line or column of it—is the mean variability of pairs of leaves, each pair chosen from one tree, and having one leaf of a particular character; it may therefore be taken as a fair measure of the variability of such a tree. We see therefore that while leaves, gathered in equal numbers from each of 100 trees, are distributed about their mean with a standard deviation of 1·735 veins, the leaves gathered from a single tree are distributed about their mean with a standard deviation of 1·426 veins, the ratio between variability of the race and variability of the individual tree being $\sqrt{1-(0\cdot5699)^2}=0\cdot822$.

The correlation between undifferentiated sets of serial homologues, produced by a single individual, is the measure of what Pearson has called homotyposis. In an elaborate memoir on the homotyposis in plants (*Phil. Trans.*, vol. 197 A., 1901), from which the foregoing statements about beech leaves are taken, Pearson has given the correlation between such sets of organs in a large number of plants: he and his pupils have subsequently determined the correlation between structures repeated in the bodies of individual animals. The results obtained are sometimes puzzling, because it is sometimes difficult to choose the whole series of structures osberved from a region of the body which is not affected by differentiation. In spite of this difficulty, however, the values of the correlation coefficients so far obtained cluster fairly well round the mean value of all of them, which is almost exactly $\frac{1}{2}$. From this result it follows (see PROBABILITY) that the standard deviation of the array, which we have taken as a measure of individual variability, is equal to the standard deviation of the race multiplied by $\sqrt{1-\left(\frac{1}{2}\right)^2}$ or by $\frac{\sqrt{3}}{2}$. These results cannot be accepted as final, but they are based on so many investigations of animals and plants, of such widely different kinds, that they may confidently be expected to hold for large classes of organic characters. We may therefore conclude that for large classes of characters, both animal and vegetable, the variability of an individual, as measured by the standard deviation of its undifferentiated but repeated organs, is a constant fraction of the variability of its race, as measured by the standard deviation of the corresponding series of organs produced by all the individuals of its race.

Among the most important structures produced in repeated series are the reproductive cells; and Pearson points out that if the variability of animals or of plants be supposed to depend upon that of the germ-cells from which they arise, then the correlation between brothers in the array produced by the same parents will give a measure of the correlation between the parental germ-cells, the determination requiring, of course, the same precautions to avoid the effects of differentiation as are necessary in the study of other repeated organs. After a large series of measurements, involving the most varied characters of human brothers, Pearson has shown that the correlation has a value very nearly equal to $\frac{1}{2}$; so that the variability of human children obeys the same law as that of other repeated structures, the standard deviation of an array, produced by the same parents, having an average value equal to the standard deviation of the whole filial generation multiplied by $\sqrt{1-\left(\frac{1}{2}\right)^2}$ or by $\frac{\sqrt{3}}{2}$. Such measurements of fraternal correlation in the lower animal as Pearson and his pupils have at present made give values very close to $\frac{1}{2}$. The evidence that the correlation between sexually produced brethren is the same as that existing between the asexually repeated organs on an individual body renders it impossible to accept Weismann's view that one of the results produced by the differentiation of animals and plants into two sexes is an increase in the variability of their offspring. Warren has shown by direct observation that the correlation between brothers among the broods produced parthenogenetically by one of the *Aphides* has a value not far from the $\frac{1}{2}$ observed in sexually produced brethren (*Biometrika*, vol. i., 1902); he has obtained a fairly concordant result for the broods of parthenogenetic *Daphnia* (*Proc. Roy. Soc.* vol. lxv., 1899). Finally, Simpson has measured the correlation between the pairs of young produced by the simple asexual division of *Paramoecium* (*Biometrika*, vol. i. part 4, 1902), and after some necessary corrections the value he obtains is 0.56, a value which probably does not, if we remember the difficulties of the inquiry, differ very significantly from $\frac{1}{2}$. There is therefore in a large class of cases an indication that the variability of an array of brethren, produced either sexually or asexually, is a constant fraction of the variability of the race to which the brethren belong.

Variation and Mendelism.—The conceptions of the disciples of Mendel, amongst whom W. Bateson is pre-eminent, would appear to simplify the problem of variation, especially on its mechanical and physiological sides. Their experimental work shows that many facts of inheritance correspond with the theory that the essential fabric of an organism is a mosaic of unit characters. Such units frequently occur in pairs, one member of the pair being characterized by the presence, the other by the absence of a problematical body at least comparable with a ferment, the result of the presence or absence being a notable modification of the whole organism or of parts of it. According to their view, in the formation of the germ cells a segregation of the unit pairs occurs—that is to say, the peculiar body or ferment is handed on to one daughter-cell but not to the other. A similar kind of segregation may take place in the formation of the repeated parts of an organism, so that symmetrical repetition may be compared with normal heredity, and be due to the presence of similar factors in the divisions of the embryonic cells, whilst the differentiation of repeated parts may be due to the unequal distribution of such factors and be comparable with variation. On such an interpretation, variation would result from asymmetrical division and normal inheritance from symmetrical division. It is equally clear that there is a broad analogy between the kind of characters on which systematists often have to rely for the separation of species and those which Mendelian workers have shown to behave in accordance with the Mendelian theories of mosaic inheritance with segregation. The analogy possibly may be extended to such cases as the occurrence of flora or fauna with alpine characters on the summits of mountains separated by broad zones of tropical climate. Segregated inheritance may have produced the appropriate combinations which were latent in the capacities of the race, and the exigencies of the environment protected them in the suitable localities. It is to be noticed, however, that the Mendelian conceptions are in no sense an alternative to Darwinism; at the most they would serve to assist in explaining the mechanism of variation, and by enlarging our idea of the factors, increase the rate at which we may suppose selection to work.

Limitation of Variations; Orthogenesis.—Darwin and his generation were deeply imbued with the Butlerian tradition, and regarded the organic world as almost a miracle of adaptation, of the minute dovetailing of structure, function and environment. Darwin certainly was impressed with the view that natural selection and variation together formed a mechanism, the central product of which was adaptation. From the Butlerian side, too, came the most urgent opposition to Darwinism. How is it possible, it was said, that fortuitous variations can furnish the material for the precise and balanced adaptations that all nature reveals? Selection cannot create the materials on which it is supposed to operate; the beginnings of new organs, the initial stages of new functions cannot be supposed to have been useful. Moreover, many naturalists, especially those concerned with palaeontology, pointed to the existence of orthogenetic series, of long lines of ancestry, which displayed not a sporadic differentiation in every direction, but apparently a steady and progressive march in one direction. E. D. Cope put such a line of argument in the most cogent fashion; the course of evolution, both in the production of variations and their selection, seemed to him to imply the existence of an originative, conscious and directive force, for which he invented the term "bathmism" (Gr. βαθμός, a step or beginning). On the other hand, dislike of mystical interpretations of natural facts has driven many capable naturalists to another extreme and has led them to insist on the "all-powerfulness of natural selection" and on the complete indefiniteness of variation. The apparent opposition between the conflicting schools is more acute than the facts justify. Both sides concur in the position assumed by Darwin, that the word "chance" in such a phrase as "chance variation" does not mean that the occurrences are independent of natural causation and so far undetermined, but covers in the first place our ignorance of the exact causation. The implication of the phrase may go farther, suggesting that there is no connexion between the appearance of the variation and the use to which it may be put. No doubt a large amount of variation is truly indefinite, so that many meaningless or useless variations arise, and in one sense it is a mere coincidence if a particular variation turn out to be useful. But there are several directions in which the field of variation appears to be not only limited but defined in a certain direction. Obviously variations depend on the constitution of the varying organism; a modification, whether it be large or small, is a modification of an already definite and limited structure. When beetles, or medusae, or cats vary, the range of possible variation is limited and determined by the beetle, medusa or cat constitution, and any possible further differentiation or specialization must be in a sense at least orthogenetic—that is to say, a continuation of the line along which the ancestors of the individual in question have been forced. Darwin himself showed that different species in a genus, or varieties in a species, tended to show parallel variations, whilst comparative anatomy has made known a multitude of cases where allied series of animals or plants show successive stages of parallel but independent variations of important organs and functions. The phenomena of convergence are to some extent other instances of the same kind and supply evidence that organisms, so to say, fall into grooves, that their possibilities of change are defined and limited by their past history. Variation, again, as has been shown in this article, is limited by correlation; as any change involves other changes, the possibilities are limited by the organic whole. Finally, it is important to remember that the fundamental characteristic of a living organism is its power of response to environment, a response or series of responses being necessary in a continuous environment for the normal facies of the organism to appear, and necessary in a shifting environment if the organism is to change suitably and not to perish. A continuous environment both from the point of view of production of variation and selection of variation would appear necessarily to result in a series with the appearance of orthogenesis. The past history of the organic world displays many successful series and these, as they have survived, must inevitably display orthogenesis to some extent; but it also displays many failures which indeed may be regarded as showing that the limitation of variation has been such that the organisms have lost the possibility of successful response to a new environment.

Selection and Adaptation.—Although knowledge of variation has become much wider and more definite, the estimation in which natural selection is held has changed very little since Darwin and Wallace first expounded their theories. Variation provides the material for selection, and although opinions may differ as to the nature of that material, the modes by which it comes into existence and their relative values and permanences, there is an increasingly wide consensus of opinion that all such material has to pass through the sieve of natural selection and that the sifted products form new varieties and species, and new adaptations. It appears to be necessary to distinguish between the production of species and the production of adaptation. We have still to admit with Darwin that it is difficult or impossible to assign utility to all the characters that distinguish species, and particularly to those characters by which systematists identify species. The modern tendency for a more complete and detailed separation of individual forms into specific and sub-specific groups, and the immensely larger range of material at the disposal of systematic experts, have combined to make it increasingly difficult to imagine conditions of the environment under which the species of systematists would have been produced by selection. On the other hand, the work of modern systematists shows an extraordinarily exact relation between their species and geographical locality, and the fact of divergent evolution can be almost demonstrated in museum collections when localities have been recorded exactly. The decision as to whether it is the course of variation or the course of selection that has been different in different localities can be made only by the field naturalist and the experimental breeder.

With regard to adaptations, it is becoming more and more apparent, as experimental knowledge advances, that it is a fundamental property of every living organism in every stage of its existence to display adaptive response to its environment. To what extent such responses are transmitted to offspring, and what part they play in the formation of the adaptive characters that are conspicuous in many animals, remain dubious, but it is at least clear that natural selection can favour those individuals and those races which show the greatest power of responsive plasticity in the individual. There remains open a wide field for inquiry as to the precise relations between selection and variation on the one hand, and their products, specific differences and adaptive structures, but the advance of knowledge has supplied no alternative to the Darwinian principles.

In the broadest way variation in organisms is primarily the necessary result of the absence of uniformity in the distribution of physical forces on the globe, in fact is a mere necessary response to the variation of inorganic conditions. So, also, in the broadest way, the result of the existence of variation is equally inevitable. Some individuals happen to fit the environment better, or to respond to the environment better, and these on the average will survive their less fortunate neighbours. It is plain that whilst the existence of variation can be demonstrated and the occurrence of evolution established by induction and deduction, the part played by selection must remain largely theoretical.

We append, however, again from the late Professor Weldon's article, a summary of the lines on which it seems possible that the actual process of selection may be demonstrated.

Selection and its results can be adequately studied only in those cases which admit of statistical tabulation. In any race of animals, the number of young produced in a season is almost always greater than the number which survives to attain maturity; it is not certain that every one of those which become mature will breed, and not all of those which breed contribute an equal number of offspring to the next generation. At every stage some individuals are prevented from contributing to the next generation, and if the continual process of elimination affects individuals possessing any one character more strongly than it affects others, so that a relation is established between individual character and the chance of producing a certain number of young, selection is said to occur.

We may distinguish broadly two ways by which such selective elimination of individuals from the number of those who contribute to the next generation may occur, viz. a *differential destruction*, which prevents certain classes of individuals from breeding by killing them, and a series of processes leading to *differential fertility* among the survivors, without necessarily involving any differential death-rate. A third form of selection, which may affect the composition of the next generation without of necessity involving a differential death-rate or a differential fertility, is *assortative mating*, or the tendency of those members of one sex which exhibit a particular character to mate only with members of the other sex which exhibit the same or some other definite character.

Differential fertility may be induced in either of two ways. Individuals may not be able to pair unless they possess a character which is absent, or insufficiently developed, in some members of the race. The kind of selection involved may then be measured by comparing those animals which pair with the general body of adults. This is what Darwin especially intended to denote by the term "sexual selection." Or, again, individuals of certain character may be able to pair, but the fertility of their union may not be the same as that of unions between individuals with other characters. This kind of selection, called by Pearson "reproductive" or "genetic" selection, may be measured by finding the correlation between the characters of the individuals which pair and the number of young produced. For an attempt to treat the whole problem of differential fertility and assortative mating numerically, see Pearson, *The Grammar of Science*, 2nd edition, London, 1900.

Assortative mating exists when individuals which mate are not paired at random, but a definite correlation is established between the characters of one mate and those of the other. This kind of selection is measured by the correlation between deviation of either mate from the type, and deviation of the other. Pearson has shown that Galton's function has a value of 0·28 for stature of middle-class Englishmen and their wives.

(P. C. M.)

VARIATIONS, in music, the term given to groups of progressively developed versions of a complete self-contained theme, retaining the form of that theme though not necessarily its melody. This at least is the classical sense of the term, though there are modern developments of the variation form to which this definition is at once too broad and too precise to apply. The aesthetic principle of variations appeared at very early stages of music; and it soon became something far more definite than the use of ornamental versions of a melodic phrase, a use which must have been natural almost as soon as music was articulate at all. During the 16th century principles aesthetically indistinguishable from some types of variation-form inevitably arose in the polyphonic treatment of Gregorian hymns verse by verse. Accordingly, the hymns and Magnificats of Palestrina might without great extravagance be described as contrapuntal sets of variations on ecclesiastical tunes, like very free examples of the type shown later in extreme simplicity and formality by Haydn's variations on his Austrian national anthem in the "Emperor" quartet (*Op.* 76, No. 3).

Already in the 16th century instrumental music was assuming such independence as it could attain by means of a primitive variation-form, growing partly out of the habit of playing vocal madrigals on the virginals or similar keyed instruments, or singing the top part as a solo to an instrumental accompaniment, with an overwhelming weight of ornaments beneath which the original madrigal was quite unrecognizable. (See, for example, the "diminutions" given in the 30th volume of Breitkopf & Härtel's complete edition of Palestrina's works.) A favourite plan, of which numerous examples may be found in the *Fitzwilliam Virginal Book*, was to put together several popular or original tunes, with an ornamental variation sandwiched between each. Sometimes, however, sets of variations on a single tune were produced, with essentially modern effect, as in Byrd's variations on "The Carman's Whistle." Such variations were naturally grouped in order of increasing complexity and brilliance. Some of the keyboard passages in which the early English variation-writers indulged are of extraordinary difficulty, even from the standpoint of modern pianoforte technique.

In the 17th century a highly artistic form of variation arose, very favourable to the earliest composers of the transition period, because of the simplicity of its principle, which relieved the composer of all the graver problems of formal organization. This was the *ground-bass*, a single phrase placed in the bass and repeating itself as long as the composer had fresh harmonies and superstructure with which to vary it. In typical examples the ground-bass was derived from the dance forms of the *passacaglia* and the *chaconne*, which in classical music resembled each other in being in slow time, and did not otherwise differ markedly, except that in the *passacaglia* the theme could be transferred now and then to the treble or to an inner part, a purely natural aesthetic resource which makes no radical difference to the art-form. The genius of Purcell was cruelly hampered by the lack of possibilities for organizing large musical forms in his time, and nothing is more significant than the avidity with which he seizes upon the ground-bass as a means of giving coherence to his ideas.

By the time of Bach and Handel a lighter type of variation-work, less capable of high organization, and more like Byrd's variations on "The Carman's Whistle," had arisen. Bach's *Aria variata alla maniera Italiana* is an instance of this; and so is the *air et doubles* that appears now and then in Handel's instrumental works. The principle of this form is simply to take a symmetrical melody (generally in binary form) and embroider it. Such variations are called *doubles* whenever each variation divides the rhythm systematically into quicker notes than the one before. The most familiar example is that known as "The Harmonious Blacksmith" in Handel's E major suite. Sometimes the air itself was stated in a tangle of ornamentation, while the *doubles* made it float in a simplified form over an accompaniment of increasingly rapid flow. (See, for example, Handel's D minor suite and the little set in B flat on a theme afterwards varied in the noblest modern style by Brahms.)

But Bach had meanwhile applied the principle of the ground-bass to variations on a complete symmetrical movement in binary form. His Air and 30 Variations, commonly known as the "Goldberg" variations, is (with the exception of Beethoven's 33 *Veränderungen* on a waltz by Diabelli) not only the most gigantic set of variations in the world, but one of the three largest compositions in any form ever written for a single instrument. Of course in so large a work the conception of the ground-bass, as a clearly recognizable theme repeated with no more than slight ornament, would be inadequate whatever the variety of the superstructure: but so steady is the drift of Bach's bass that he is enabled to represent it by countless alternative harmonies and analogous chromatic progressions, without weakening its individuality. The grouping of the thirty variations is extremely subtle in balance and climax; the more so because there are no means within the terms of Bach's art for making a free coda to the work, his ground-bass being both too long and too purely a bass to be taken as the theme of a fugue, like that in his great *passacaglia* for organ. Yet Bach contrives to round off the work perfectly by the simple direction *aria da capo* at the end. There is no question of retaining or varying the melody of the aria, which indeed is so ornamental as to be pointless and unrecognizable as a basis for variations; nor could it, like the above-mentioned Italian examples of Handel, be simplified, since most of its ornaments are integral parts of the phrases.

The next chapter in the history of the variation form is intimately connected with the sonata style. A set of variations used as a movement for a sonata inevitably tends to be variations on the melody. The sonata style implies the identification of themes by their melodies rather than by their texture, the very term "theme" being primarily used in a melodic connotation (see MELODY). Hence a set of exclusively harmonic variations would not be in the sonata style. Now, most of the best sets of variations by Mozart and Haydn are movements in their sonata works; and this should always be remembered in discussing the tendency of their treatment of the form. Few of their independent sets are of any importance, since most are very early works, or were written for pupils, or intended as encore pieces for concerts. Haydn shows a great fondness for a special form which, even if earlier specimens can be found, he may properly be said to have invented. It consists of alternating variations on two themes, the first a highly organized complete binary melody, and the other a shorter binary melody, often beginning with the same figure as the first, but clearly contrasted with it, inasmuch as, whichever theme is in the major, the other is in the minor. The first theme usually returns as if it were going to be unvaried, but its first repeat is an ornamental variation. The form is rarely worked out far enough to include more than one variation of the second theme; but the effect is always that of a happy blend of a clearly marked variation form with a more contrasted scheme a little more highly organized than the round-and-round symmetry of a minuet and trio, but not so elaborate as a rondo. The only later example exactly corresponding to Haydn's form is the first allegretto of Beethoven's pianoforte trio in E flat, *Op.* 70, No. 2; although, with a wider range of key, a free application of the principle of alternating themes is magnificently illustrated by the slow movement of his C minor symphony.

Beethoven in his last works invented another variation-form on two themes, in which the first theme is very free in structure and the second theme is a more rigid melody in a different key and time. The examples of this are the slow movement of the 9th Symphony and the Lydian figured chorale in the A minor quartet. A fine later development of this is the slow movement of Brahms's F major string quintet, *Op.* 88, in which the alternation of the two keys gives rise, in the last line of the movement, to one of the most astonishing and subtle dramatic strokes in all music.

In sonata works, Beethoven's examples of the normal variation form based on a single theme are as wonderful as may be expected from him; but nothing is more significant than his strict adherence in sonata works to the melodic principle of variation. He uses the form as an unsurpassable means of obtaining repose in slow movements. The extreme case of this is the slow movement of the sonata, *Op.* 57 (commonly called *Appassionata*), which is described in the article on SONATA FORMS. In this and in many other instances, his method is aesthetically that of the *air et doubles*, as being the simplest possible means of obtaining variety and climax without leaving the fundamental key. Until his latest works, such sets of variations are never finished. Their dramatic force is that of a repose which is too unearthly to last; and at the first sign of dramatic motion or change of key the sublime vision "fades into the light of common day," a light which Beethoven is far too great an idealist to despise. (See the andante of the B flat trio, *Op.* 97; and the slow movement of the violin concerto, which contains two episodic themes in the same key.) In his later works Beethoven found means, by striking out into foreign keys or foreign rhythms, of organizing a coda which, as it were, finally spins down in fragmentary new variations, or even returns to the plain theme. Thus he was able to end his sonatas, *Opp.* 109 and 111, with solemn slow movements in which, with the utmost richness of detail and novelty of idea, the melodic variation form is nevertheless paramount. Beethoven also found many ways of combining melodic variations with the principles of the rondo and other more highly organized continuous movements. Thus the finale of the Eroica Symphony has not only the theme but many ideas of the variations and fugue-passages in common with the brilliant set of variations for pianoforte on a theme from *Prometheus*, *Op.* 35; and the Fantasia for pianoforte, chorus and orchestra, and the choral finale of the 9th Symphony, are sets of melodic variations with freely developed connecting links and episodes. In the case of the 9th Symphony, a second thematic idea eventually combines with the figures of the first theme in double fugue.

But Beethoven's highest art in variation-form is to be found in his independent sets of variations. In some of the earliest of these, notably in the 24 on a theme by Righini (which was his chief bravura performance as a young pianoforte player), he far transcends not only the earlier or sonata-form idea of melodic variations, but fuses their resources with those of the ground-bass, and adds to them his own unparalleled grasp of rhythmic organization. Beethoven is the first composer who can be said to have discovered that a theme consists not only of melody and harmony but of rhythm and form. With earlier composers the form of the theme was automatically preserved in consequence of the preservation of either its melody or its harmony; but Beethoven had an unerring judgment as to when the form of a theme might be definite enough to remain as a basis for a variation which departed radically from both the harmony and the melody. The climax in the history of variations dates from the moment when Beethoven was just about to begin his 9th Symphony, and received from A. Diabelli a waltz which that publisher was sending round to all the musicians in Austria so that each might contribute a variation to be published for the benefit of the sufferers in the late Napoleonic wars. Diabelli's theme was absurdly prosaic, but it happened to be perhaps the sturdiest piece of musical anatomy that Beethoven or any composer since has ever seen. Not only was its harmonic form exceptionally clear and firm, but its phrase-rhythm was as simple, recognizable and heterogeneous as its other qualities. Its melodic merit was nil, yet it had plenty of recognizable melodic figures. All these prosaic technicalities are far more likely to impress a great composer as good practical resources than those high poetic qualities which critics discuss incessantly, but which are to a great artist the air he breathes. Diabelli's waltz moved Beethoven to defer his work on the 9th Symphony!

The shape of Diabelli's theme may be illustrated by a diagram

Tonic. Dominant. Rising sequence. Close in dominant.

which represents its first sixteen bars; the upright strokes being the bars, and the brackets and dots (together with the names underneath) indicating the way in which the rhythm is grouped by correspondence of phrase and changes of harmony. The second part also consists of sixteen bars, moving harmonically back from the dominant to the tonic, and rhythmically of exactly the same structure as the first part. This harmonic and sequential plan, together with this straightforward square tapering rhythmic structure, is so formal in effect that Beethoven can substitute for it almost anything equally familiar that corresponds in its proportions. Thus, the alternation of tonic and dominant in the first eight bars may be represented by another familiar form in which three bars of tonic and a fourth of dominant are answered by three bars of dominant and a fourth of tonic; as in variation 14 (which must be reckoned in half-bars). Again, the antithesis of tonic and dominant is accompanied in Diabelli's theme by a part of the melodic figure being repeated a step higher at the change of harmony; and this naturally produces such devices as the answering of the tonic by the supertonic in variation 8, and, still more surprisingly, by the flat supertonic in variation 30. In so enormous and resourceful a work, occupying fifty minutes in performance, it is natural that some variations should drift rather farther from the anatomy of the theme than can be explained by any strict principle; and so the jocular transformation of the beginning of Diabelli's bass into the theme of Mozart's *Notte e giorno faticar* leads to a couple of extra bars at the end of its second part; otherwise the *fughetta* (variation 24) and variations 29 and 31 are the only cases in which any considerable part of the structure of the theme is lost, except the fugue (variation 32), which is simply an elaborate movement on a salient feature of what must by courtesy be called Diabelli's melody. A free fugue is a favourite solution of the difficult problem of the coda in a set of variations.

But for the works of Brahms, which invariably retain the classical conceptions while developing them in a thoroughly modern and living language, it can hardly be claimed that the art of variation-writing has advanced since Beethoven. The term is now used for a somewhat nondescript method of stringing together a series of short fantasias on a theme; a method which may be legitimate and artistic in individual cases, but hardly constitutes an art-form. There is this great disadvantage in variations that neglect the anatomy of the theme, that the only way in which, in the absence of other means of connexion, they can show any coherence at all is by more or less frequently harping on scraps of the melody. The effect is (except in unusually happy examples such as the *Études symphoniques* of Schumann and the *Enigma Variations* of Elgar) curiously apologetic; because no ambitious composer in the "free" modern variation style thinks a melodic variation quite worthy of his dignity, and so the melodic allusions become the more tiresome from their furtive manner. Many "advanced" specimens of variation-form undoubtedly owe their origin to a vague impulse of revolt from the unsound statements of unobservant writers of mid-19th century text-books, who contented themselves with laying down crude rules such as that a variation might "either retain the melody and change the harmony, or retain the harmony and change the melody," &c., without any attempt to see how the classical composers really analysed their themes. It is very characteristic of Schumann's modesty and grasp of facts that he, who was the first to produce serious art in a free non-anatomical variation style, did not call his experiments variations without qualification. He never wrote a set in which the anatomy of the theme was of real importance to the whole; and, with him, whenever at least the initial melodic figure of his theme is not traceable throughout a section, that section is simply an episode. But Schumann knows this perfectly well, and acknowledges it. The *Études symphoniques* are called variations only in those sections which are fairly strict variations. Elsewhere they are simply numbered as *études*. The slow movement of the F major string quartet (in which a second theme masquerades as the first variation, and some of the other variation-like sections are quite free) is called *andante quasi variazione*; and even the strictest of all his variation works is called *Impromptus, on a theme by Clara Wieck*, *Op.* 5. There is, no doubt, great scope for a variation-form which is neither melodic nor anatomic, and we have not a word to say against the legitimacy of many forms of effective modern fantasia-variations; but the fact remains that it is very hazardous to talk of an "advance" in the variation-form, when even the best fantasia-variations are not only unconnected with any classical type but evidently unable to get nearly as far from either the melody or the harmony of their theme as the 25th of Bach's "Goldberg" variations or many variations in the earliest sets by Beethoven. Indeed, the only sound classification of composers of modern variations, from the time of Mendelssohn onwards, is that which distinguishes the composers who seem to know their theme from those who do not. (D. F. T.)

VARIATIONS, CALCULUS OF, in mathematics. The calculus of variations arose from the attempts that were made by mathematicians in the 17th century to solve problems of which the following are typical examples. (i) It is required to determine the form of a chain of given length, hanging from two fixed points, by the condition that its centre of gravity must be as low as possible. This problem of the *catenary* was attempted without success by Galileo Galilei (1638). (ii) The resistance of a medium to the motion of a body being assumed to be a normal pressure, proportional to the square of the cosine of the angle between the normal to the surface and the direction of motion, it is required to determine the meridian curve of a surface of revolution, about an axis in the direction of motion, so that the resistance shall be the least possible. This problem of the *solid of least resistance* was solved by Sir Isaac Newton (1687). (iii) It is required to find a curve joining two fixed points, so that the time of descent along this curve from the higher point to the lower may be less than the time along any other curve. This problem of the *brachistochrone* was proposed by John (Johann) Bernoulli (1696).

Origin of the Calculus.

The contributions of the Greek geometry to the subject consist of a few theorems discovered by one Zenodorus, of whom little is known. Extracts from his writings have been preserved in the writings of Pappus of Alexandria and Theon of Smyrna. He proved that of all curves of given perimeter the circle is that which encloses the largest area. The problems from which the subject grew up have in common the character of being concerned with the maxima and minima of quantities which can be expressed by integrals of the form

Early history.

$$\int_{x_0}^{x_1} F(x, y, y')dx,$$

in which y is an unknown function of x, and F is an assigned function of three variables, viz. x, y, and the differential coefficient of y with respect to x, here denoted by y'; in special cases x or y may not be explicitly present in F, but y' must be. In any such problem it is required to determine y as a function of x, so that the integral may be a maximum or a minimum, either absolutely or subject to the condition that another integral or like form may have a prescribed value. For example, in the problem of the catenary, the integral

$$\int_{x_0}^{x_1} y(1+y'^2)^{\frac{1}{2}}dx$$

must be a minimum, while the integral

$$\int_{x_0}^{x_1} (1+y'^2)^{\frac{1}{2}}dx$$

has a given value. When, as in this example, the length of the sought curve is given, the problem is described as *isoperimetric.* At the end of the first memoir by James (Jakob) Bernoulli on the infinitesimal calculus (1690), the problem of determining the form of a flexible chain was proposed. Gottfried Wilhelm Leibnitz gave the solution in 1691, and stated that the centre of gravity is lower for this curve than for any other of the same length joining the same two points. The first step towards a theory of such problems was taken by James Bernoulli (1697) in his solution of the problem of the brachistochrone. He pointed out that if a curve, as a whole, possesses the maximal or minimal property, every part of the curve must itself possess the same property. Beyond the discussion of special problems, nothing was attempted for many years.

The first general theory of such problems was sketched by Leonhard Euler in 1736, and was more fully developed by him in his treatise *Methodus inveniendi* . . . published in 1744. He generalized the problems proposed by his predecessors by admitting under the sign of integration differential coefficients of order higher than the first. To express the condition that an integral of the form

Euler.

$$\int_{x_0}^{x_1} F(x, y, y', y'', \dots y^{(n)})dx$$

may be a maximum or minimum, he required that, when y is changed into $y+u$, where u is a function of x, but is everywhere "infinitely" small, the integral should be unchanged. Resolving the integral into a sum of elements, he transformed this condition into an equation of the form

$$\Sigma u\Delta x\left[\frac{\partial F}{\partial y}-\frac{d}{dx}\frac{\partial F}{\partial y'}+\frac{d^2}{dx^2}\frac{\partial F}{\partial y''}-\dots+(-1)^n\frac{d^n}{dx^n}\frac{\partial F}{\partial y^{(n)}}\right]=0,$$

and he concluded that the differential equation obtained by equating to zero the expression in the square brackets must be satisfied. This equation is in general of the $2n$th order, and the $2n$ arbitrary constants which are contained in the complete primitive must be adjusted to satisfy the conditions that $y, y', y'', \dots y^{(n-1)}$ have given values at the limits of integration. If the function y is required also to satisfy the condition that another integral of the same form as the above, but containing a function ϕ instead of F, may have a prescribed value, Euler achieved his purpose by replacing F in the differential equation by $F+\lambda\phi$, and adjusting the constant λ so that the condition may be satisfied. This artifice is known as the *isoperimetric rule* or *rule of the undetermined multiplier.* Euler illustrated his methods by a large number of examples.

The new theory was provided with a special symbolism by Joseph Louis de la Grange (commonly called Lagrange) in a series of memoirs published in 1760–62. This symbolism was afterwards adopted by Euler (1764), and Lagrange is generally regarded as the founder of the calculus of variations. Euler had been under the necessity of resolving an integral into a sum of elements, recording the magnitude of the change produced in each element by a slight change in the unknown function, and thence forming an expression for the total change in the sum under consideration. Lagrange proposed to free the theory from this necessity. Euler had allowed such changes in the position of the curve, along which the integral, to be made a maximum or minimum, is taken, as can be produced by displacement parallel to the axis of ordinates. Lagrange admitted a more general change of position, which was called *variation.* The points of the curve being specified by their co-ordinates, x, y, z, and differentiation along the curve being denoted, as usual, by the symbol d, Lagrange considered the change produced in any quantity Z, which is expressed in terms of $x, y, z, dx, dy, dz, d^2x, \dots$ when the co-ordinates x, y, z are changed by "infinitely" small increments. This change he denoted by δZ, and regarded as the variation of Z. He expressed the rules of operation with δ by the equations

Lagrange.

$$\delta dZ = d\delta Z,\quad \delta\int Z = \int\delta Z.$$

By means of these equations $\int\delta Z$ can be transformed by the process of integration by parts into such a form that differentials of variations occur at the limits of integration only, and the transformed integral contains no differentials of variations. The terms at the limits and the integrand of the transformed integral must vanish separately, if the variation of the original integral vanishes. The process of freeing the original integral from the differentials of variations results in a differential equation, or a system of differential equations, for the determination of the form of the required curve, and in special terminal conditions, which serve to determine the constants that enter into the solution of the differential equations. Lagrange's method lent itself readily to applications of the generalized principle of virtual velocities to problems of mechanics, and he used it in this way in the *Mécanique analytique* (1788). The terminology and notation of mechanics are still largely dominated by these ideas of Lagrange, for his methods were powerful and effective, but they are rendered obscure by the use of "infinitely" small quantities, of which, in other departments of mathematics, he subsequently became an uncompromising opponent. The same ideas were applied by Lagrange himself, by Euler, and by other mathematicians to various extensions of the calculus of variations. These include problems concerning integrals of which the limits are variable in accordance with assigned conditions, the extension of Euler's rule of the multiplier to problems in which the variations are restricted by conditions of various types, the maxima and minima of integrals involving any number of dependent variables, such as are met with in the formulation of the dynamical Principle of Least Action, the maxima and minima of double and multiple integrals. In all these cases Lagrange's methods have been applied successfully to obtain the differential equation, or system of differential equations, which must be satisfied if the integral in question is a maximum or a minimum. This equation, or equations, will be referred to as the *principal equation*, or principal equations, of the problem.

The symbol δ.

Extensions of Lagrange's method.

The problems and method of the calculus admit of more exact formulation as follows: We confine our attention to the case where the sought curve is plane, and the function F contains no differential coefficients of order higher than the first. Then the problem is to determine a curve joining two fixed points (x_0, y_0) and (x_1, y_1) so that the *line integral*

Formulation of the First Problem.

$$\int_{x_0}^{x_1} F(x, y, y')dx$$

taken along the curve may be a maximum or a minimum. When it is said that the integral is a minimum for some curve, it is meant that it must be possible to mark a finite area in the plane of (x, y), so that the curve in question lies entirely within this area, and the integral taken along this curve is less than the integral taken along any other curve, which joins the same two points and lies entirely within the delimited area. There is a similar definition for a maximum. The word *extremum* is often used to connote both maximum and minimum. The problem thus posed is known as the *First Problem of the Calculus of Variations.* If we begin with any curve joining the fixed end points, and surround it by an area of finite breadth, any other curve drawn within the area, and joining the same end points, is called a *variation* of the original curve, or a *varied curve*. The original curve is defined by specifying y as a function of x. Necessary conditions for the existence of an extremum can be found by choosing special methods of variation.

One method of variation is to replace y by $y+\epsilon u$, where u is a function of x, and ϵ is a constant which may be taken as small as we please. The function u is independent of ϵ. It is differentiable, and its differential coefficient is continuous within the interval of integration. It must vanish at $x=x_0$ and at $x=x_1$. This method of variation has the property that, when the ordinate of the curve is but slightly changed, the direction of the tangent is but slightly changed. Such variations are called *weak variations*. By such a variation the integral is changed into

Weak variations.

$$\int_{x_0}^{x_1} \mathrm{F}(x,\ y+\epsilon u,\ y'+\epsilon u')dx,$$

and the increment, or variation of the integral, is

$$\int_{x_0}^{x_1}\{\mathrm{F}(x,y+\epsilon u,\ y'+\epsilon u')-\mathrm{F}(x,\ y,\ y')\}dx.$$

In order that there may be an extremum it is necessary that the variation should be one-signed. We expand the expression under the sign of integration in powers of ϵ. The first term of the expansion contributes to the variation the term

The first variation.

$$\epsilon\int_{x_0}^{x_1}\left(\frac{\partial \mathrm{F}}{\partial y}u+\frac{\partial \mathrm{F}}{\partial y'}u'\right)dx.$$

This term is called the *first variation*. The variation of the integral cannot be one-signed unless the first variation vanishes. On transforming the first variation by integration by parts, and observing that u vanishes at $x=x_0$ and at $x=x_1$, we find a necessary condition for an extremum in the form

$$\int_{x_0}^{x_1}\left(\frac{\partial \mathrm{F}}{\partial y}-\frac{d}{dx}\frac{\partial \mathrm{F}}{\partial y'}\right)u\,dx=0.$$

It is a fundamental theorem that this equation cannot hold for all admissible functions u, unless the differential equation

$$\frac{d}{dx}\frac{\partial \mathrm{F}}{\partial y'}-\frac{\partial \mathrm{F}}{\partial y}=0$$

is satisfied at every point of the curve along which the integral is taken. This is the principal equation for this problem. The curves that are determined by it are called the *stationary curves*, or the *extremals*, of the integral. We learn that the integral cannot be an extremum unless it is taken along a stationary curve.

Stationary curves.

A difficulty might arise from the fact that, in the foregoing argument, it is tacitly assumed that y, as a function of x, is one-valued; and we can have no a priori ground for assuming that this is the case for the sought curve. This difficulty might be met by an appeal to James Bernoulli's principle, according to which every arc of a stationary curve is a stationary curve between the end points of the arc—a principle which can be proved readily by adopting such a method of variation that the arc of the curve between two points is displaced, and the rest of the curve is not. But another method of meeting it leads to important developments. This is the method of parametric representation, introduced by K. Weierstrass. According to this method the curve is defined by specifying x and y as one-valued functions of a parameter θ. The integral is then of the form

Parametric method.

$$\int_{\theta_0}^{\theta_1} f(x,\ y,\ \dot{x},\ \dot{y})d\theta,$$

where the dots denote differentiation with respect to θ, and f is a homogeneous function of $\dot{x}$, $\dot{y}$ of the first degree. The mode of dependence of x and y upon θ is immaterial to the problem, provided that they are one-valued functions of θ. A weak variation is obtained by changing x and y into $x+\epsilon u$, $y+\epsilon v$, where u and v are functions of θ which have continuous differential coefficients and are independent of ϵ. It is then found that the principal equations of the problem are

$$\frac{d}{d\theta}\frac{\partial f}{\partial \dot{x}}-\frac{\partial f}{\partial x}=0,\ \frac{d}{d\theta}\frac{\partial f}{\partial \dot{y}}-\frac{\partial f}{\partial y}=0.$$

These equations are equivalent to a single equation, for it can be proved without difficulty that, when f is homogeneous of the first degree in $\dot{x}$, $\dot{y}$

$$\frac{1}{\dot{y}}\left\{\frac{d}{d\theta}\frac{\partial f}{\partial \dot{x}}-\frac{\partial f}{\partial x}\right\}=-\frac{1}{\dot{x}}\left\{\frac{d}{d\theta}\frac{\partial f}{\partial \dot{y}}-\frac{\partial f}{\partial y}\right\}=\frac{\partial^2 f}{\partial y\partial \dot{x}}-\frac{\partial^2 f}{\partial x\partial \dot{y}}+f_1(\ddot{x}\dot{y}-\ddot{y}\dot{x}),$$

where

$$f_1=\frac{1}{\dot{y}^2}\frac{\partial^2 f}{\partial \dot{x}^2}=-\frac{1}{\dot{x}\dot{y}}\frac{\partial^2 f}{\partial \dot{x}\partial \dot{y}}=\frac{1}{\dot{x}^2}\frac{\partial^2 f}{\partial \dot{y}^2}.$$

The stationary curves obtained by this method are identical with those obtained by the previous method.

The formulation of the problem by the parametric method often enables us to simplify the formation and integration of the principal equation. A very simple example is furnished by the problem: Given two points in the plane of $(x,\ y)$ on the same side of the axis of x, it is required to find a curve joining them, so that this curve may generate, by revolution, about the axis of x, a surface of minimum area. The integral to be made a minimum is

Problem of the catenoid.

$$\int_{\theta_0}^{\theta_1} y(\dot{x}^2+\dot{y}^2)^{\frac{1}{2}}d\theta,$$

and the principal equation is

$$\frac{d}{d\theta}\left\{\frac{y\dot{x}}{(\dot{x}^2+\dot{y}^2)^{\frac{1}{2}}}\right\}=0,$$

of which the first integral is

$$y\dot{x}(\dot{x}^2+\dot{y}^2)^{-\frac{1}{2}}=c,$$

or

$$\frac{y}{c}=\left\{1+\left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}};$$

and the stationary curves are the catenaries

$$y=c\cosh\{(x-a)/c\}.$$

The required minimal surface is the *catenoid* generated by the revolution of one of these catenaries about its directrix.

The parametric method can be extended without difficulty so as to become applicable to more general classes of problems. A simple example is furnished by the problem of forming the equations of the path of a ray of light in a variable medium. According to Fermat's principle, the integral $\int\mu ds$ is a minimum, ds representing the element of arc of a ray, and μ the refractive index. Thus the integral to be made a minimum is

Path of a ray.

$$\int_{\theta_0}^{\theta_1}\mu(\dot{x}^2+\dot{y}^2+\dot{z}^2)^{\frac{1}{2}}d\theta.$$

The equations are found at once in forms of the type

$$\frac{d}{d\theta}\left\{\mu\frac{\dot{x}}{(\dot{x}^2+\dot{y}^2+\dot{z}^2)^{\frac{1}{2}}}\right\}-\frac{\partial\mu}{\partial x}(\dot{x}^2+\dot{y}^2+\dot{z}^2)^{\frac{1}{2}}=0;$$

and, since $(\dot{x}^2+\dot{y}^2+\dot{z}^2)^{\frac{1}{2}}d\theta=ds$, these equations can be written in the usual forms of the type

$$\frac{d}{ds}\left(\mu\frac{dx}{ds}\right)-\frac{\partial\mu}{\partial x}=0.$$

The formation of the first variation of an integral by means of a weak variation can be carried out without difficulty in the case of a simple integral involving any number of dependent variables and differential coefficients of arbitrarily high orders, and also in the cases of double and multiple integrals; and the quantities of the type ϵu, which are used in the process, may be regarded as equivalent to Lagrange's δx, δy, . . . The same process may not, however, be applied to isoperimetric problems. If the first variation of the integral which is to be made an extremum, subject to the condition that another integral has a prescribed value, is formed in this way, and if it vanishes, the curve is a stationary curve for this integral. If the prescribed value of the other integral is unaltered, its first variation must vanish; and, if the first variation is formed in this way, the curve is a stationary curve for this integral also. The two integrals do not, however, in general possess the same stationary curves. We can avoid this difficulty by taking the variations to be of the form $\epsilon_1 u_1+\epsilon_2 u_2$, where ϵ_1 and ϵ_2 are independent constants; and we can thus obtain a completely satisfactory proof of the rule of the undetermined multiplier. A proof on these lines was first published by P. Du Bois-Reymond (1879). The rule had long been regarded as axiomatic.

Rule of the multiplier.

The parametric method enables us to deal easily with the problem of variable limits. If, in the First Problem, the terminal point $(x_1,\ y_1)$ is movable on a given guiding curve $\phi(x_1,\ y_1)=0$, the first variation of the integral can be written

$$\epsilon\left[u_1\frac{\partial f}{\partial \dot{x}}+v_1\frac{\partial f}{\partial \dot{y}}\right]_{x=x_1,\ y=y_1}-\epsilon\int_{\theta_0}^{\theta_1}\left[\left\{\frac{d}{d\theta}\frac{\partial f}{\partial \dot{x}}-\frac{\partial f}{\partial x}\right\}u+\left\{\frac{d}{d\theta}\frac{\partial f}{\partial \dot{y}}-\frac{\partial f}{\partial y}\right\}v\right]d\theta,$$

where $(x_1+\epsilon u_1,\ y_1+\epsilon v_1)$ is on the curve $\phi(x_1,\ y_1)=0$, and u_1, v_1 denote the values of u, v at $(x_1,\ y_1)$. It follows that the required curve must be a stationary curve, and that the condition

$$\frac{\partial f}{\partial \dot{x}}\frac{\partial\phi}{\partial y_1}-\frac{\partial f}{\partial \dot{y}}\frac{\partial\phi}{\partial x_1}=0$$

must hold at $(x_1,\ y_1)$. The corresponding condition in the case of the integral

Variable limits.

$$\int_{x_0}^{x_1}\mathrm{F}(x,\ y,\ y')dx$$

is found from the equations

$$\frac{\partial f}{\partial \dot{x}}=\mathrm{F}-y'\frac{\partial \mathrm{F}}{\partial y'},\ \frac{\partial f}{\partial \dot{y}}=\frac{\partial \mathrm{F}}{\partial y'}$$

to be

$$\mathrm{F}(x,\ y,\ y')+\left(\frac{dy_1}{dx_1}-y'\right)\frac{\partial \mathrm{F}}{\partial y'}=0.$$

This discussion yields an important result, which may be stated as follows: Let two stationary curves of the integral be drawn from the same initial point A to points P, Q, which are near together, and let the line PQ be of length ν, and make an angle ω with the axis of x (fig. 1). The excess of the integral taken along AQ, from A to Q, above the integral taken along AP, from A to P, is expressed, correctly to the first order in ν, by the formula

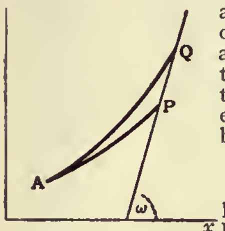

FIG. 1.

$$\nu\cos\omega\left\{F(x,y,y')+(\tan\omega-y')\frac{\partial F}{\partial y'}\right\}.$$

In this formula x, y are the co-ordinates of P, and y' has the value belonging to the point P and the stationary curve AP. When the coefficient of $\nu\cos\omega$ in the formula vanishes, the curve AP is said to be cut *transversely* by the line PQ, and a curve which cuts a family of stationary curves transversely is described as a *transversal* of those curves. In the problem of variable limits, when a terminal point moves on a given guiding curve, the integral cannot be an extremum unless the stationary curve along which it is taken is cut transversely by the guiding curve at the terminal point. A simple example is afforded by the shortest line, drawn on a surface, from a point to a given curve, lying on the surface. The required curve must be a geodesic, and it must cut the given curve at right angles.

Transversals of stationary curves.

The problem of variable limits may always be treated by a method of which the following is the principle: In the First Problem let the initial point (x_0, y_0) be fixed, and let the terminal point (x_1, y_1) move on a fixed guiding curve C_1. Now, whatever the terminal point may be, the integral cannot be an extremum unless it is taken along a stationary curve. We have then to choose among those stationary curves which are drawn from (x_0, y_0) to points of C_1 that one which makes the integral an extremum. This can be done by expressing the value of the integral taken along a stationary curve from the point (x_0, y_0) to the point (x_1, y_1) in terms of the co-ordinates x_1, y_1, and then making this expression an extremum, in regard to variations of x_1, y_1, by the methods of the differential calculus, subjecting (x_1, y_1) to the condition of moving on the curve C_1.

Alternative method.

An important example of the first variation of integrals is afforded by the Principle of Least Action in dynamics. The kinetic energy T is a homogeneous function of the second degree in the differential coefficients $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_n$ of the co-ordinates $q_1, q_2, \ldots q_n$ with respect to the time t, and the potential energy V is a function of these co-ordinates. The energy equation is of the form

$$T+V=E,$$

Principle of least action.

where E is a constant. A *course* of the system is defined when the co-ordinates q are expressed as functions of a single parameter θ. The *action* A of the system is defined as the integral $\int_{t_0}^{t_1} 2T\,dt$, *taken along a course* from the initial position $(q^{(0)})$ to the final position $(q^{(1)})$, but t_0 and t_1 are not fixed. The equations of motion are the principal equations answering to this integral. To obtain them it is most convenient to write $\Phi(\dot{q})$ for T, and to express the integral in the form

$$\int_{\theta_0}^{\theta_1} 2(E-V)^{\frac{1}{2}}\{\Phi(q')\}^{\frac{1}{2}}d\theta,$$

where q' denotes the differential coefficient of a co-ordinate q with respect to θ, and, in accordance with the parametric method, the limits of integration are fixed, and the integrand is a homogeneous function of the q''s of the first degree. There is then no difficulty in deducing the Lagrangian equations of motion of the type

$$\frac{d}{dt}\frac{\partial T}{\partial \dot{q}}-\frac{\partial T}{\partial q}+\frac{\partial V}{\partial q}=0.$$

These equations determine the actual course of the system. Now if the system, in its actual course, passes from a given initial position $(q^{(0)})$ to a variable final position (q), the action A becomes a function of the q's, and the first method used in the problem of variable limits shows that, for every q

$$\frac{\partial A}{\partial q}=\frac{\partial T}{\partial \dot{q}}.$$

When the kinetic energy T is expressed as a homogeneous quadratic function of the momenta $\partial T/\partial\dot{q}$, say

$$T=\tfrac{1}{2}\Sigma_{r,s}\left(b_{rs}\frac{\partial T}{\partial \dot{q}_r}\frac{\partial T}{\partial \dot{q}_s}\right),\ (b_{sr}=b_{rs}),$$

and the differential coefficients of A are introduced instead of those of T, the energy equation becomes a non-linear partial differential equation of the first order for the determination of A as a function of the q's. This equation is

$$\tfrac{1}{2}\Sigma_{r,s}\left(b_{rs}\frac{\partial A}{\partial q_r}\frac{\partial A}{\partial q_s}\right)+V=E.$$

Principle of varying action.

A complete integral of this equation would yield an expression for A as a function of the q's containing n arbitrary constants, $a_1, a_2, \ldots a_n$, of which one a_n is merely additive to A; and the courses of the system which are compatible with the equations of motion are determined by equations of the form

$$\frac{\partial A}{\partial a_1}=b_1,\ \frac{\partial A}{\partial a_2}=b_2,\ldots\frac{\partial A}{\partial a_{n-1}}=b_{n-1}$$

where the b's are new arbitrary constants. It is noteworthy that the differential equations of the second order by which the geodesics on an ellipsoid are determined were first solved by this method (C. G. J. Jacobi, 1839).

It has been proved that every problem of the calculus of variations, in which the integral to be made an extremum contains only one independent variable, admits of a similar transformation; that is to say, the integrals of the principal equations can always be obtained, in the way described above, from a complete integral of a partial differential equation of the first order, and this partial differential equation can always be formed by a process of elimination. These results were first proved by A. Clebsch (1858).

Principle of varying action generalized.

Among other analytical developments of the theory of the first variation we may note that the necessary and sufficient condition that an expression of the form

$$F(x, y, y', \ldots y^{(n)})$$

should be the differential coefficient of another expression of the form

$$F_1(x, y, y', \ldots y^{(n-1)})$$

Condition of integrability.

is the identical vanishing of the expression

$$\frac{\partial F}{\partial y}-\frac{d}{dx}\frac{\partial F}{\partial y'}+\frac{d^2}{dx^2}\frac{\partial F}{\partial y''}-\ldots+(-1)^n\frac{d^n}{dx^n}\frac{\partial F}{\partial y^{(n)}}.$$

The result was first found by Euler (1744).

A differential equation

$$\phi(x, y, y', y'')=0$$

is the principal equation answering to an integral of the form

$$\int F(x, y, y')dx$$

if the equation

$$\frac{d}{dx}\frac{\partial\phi}{\partial y''}=\frac{\partial\phi}{\partial y'}$$

is satisfied identically. In the more general case of an equation of the form

$$\phi(x, y, y', \ldots y^{(2n)})=0$$

Condition that a differential equation may arise from a problem of the calculus of variations.

the corresponding condition is that the differential expression obtained by Lagrange's process of variation, viz.,

$$\frac{\partial\phi}{\partial y}\delta y+\frac{\partial\phi}{\partial y'}\frac{d\delta y}{dx}+\ldots+\frac{\partial\phi}{\partial y^{(2n)}}\frac{d^{2n}\delta y}{dx^{2n}},$$

must be identical with the "adjoint" differential expression

$$\frac{\partial\phi}{\partial y}\delta y-\frac{d}{dx}\left(\frac{\partial\phi}{\partial y'}\delta y\right)+\frac{d^2}{dx^2}\left(\frac{\partial\phi}{\partial y''}\delta y\right)-\ldots+\frac{d^{2n}}{dx^{2n}}\left(\frac{\partial\phi}{\partial y^{(2n)}}\delta y\right).$$

This matter has been very fully investigated by A. Hirsch (1897).

To illustrate the transformation of the first variation of multiple integrals we consider a double integral of the form

$$\iint\psi(x, y, z, p, q, r, s, t)dxdy,$$

taken over that area of the z plane which is bounded by a closed curve s'. Here $p, q, \ldots t$ denote the partial differential coefficients of z with respect to x and y of the first and second orders, according to the usual notation. When z is changed into $z+\epsilon w$, the terms of the first order in ϵ are

First variation of a double integral.

$$\epsilon\iint\left(\frac{\partial\psi}{\partial z}w+\frac{\partial\psi}{\partial p}\frac{\partial w}{\partial x}+\frac{\partial\psi}{\partial q}\frac{\partial w}{\partial y}+\frac{\partial\psi}{\partial r}\frac{\partial^2 w}{\partial x^2}+\frac{\partial\psi}{\partial s}\frac{\partial^2 w}{\partial x\partial y}+\frac{\partial\psi}{\partial t}\frac{\partial^2 w}{\partial y^2}\right)dxdy.$$

Each term must be transformed so that no differential coefficients of w are left under the sign of double integration. We exemplify the process by taking the term containing $\partial^2 w/\partial x^2$. We have

$$\iint\frac{\partial\psi}{\partial r}\frac{\partial^2 w}{\partial x^2}dxdy=\iint\left\{\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\frac{\partial w}{\partial x}\right)-\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\right)\cdot\frac{\partial w}{\partial x}\right\}dxdy$$

$$=\iint\left[\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\frac{\partial w}{\partial x}\right)-\frac{\partial}{\partial x}\left\{w\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\right)\right\}+w\frac{\partial^2}{\partial x^2}\left(\frac{\partial\psi}{\partial r}\right)\right]dxdy.$$

The first two terms are transformed into a line integral taken round the boundary s', and we thus find

$$\iint\frac{\partial\psi}{\partial r}\frac{\partial^2 w}{\partial x^2}dxdy=\int\cos(x,\nu)\left\{\frac{\partial\psi}{\partial r}\frac{\partial w}{\partial x}-w\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\right)\right\}ds'+\iint w\frac{\partial^2}{\partial x^2}\left(\frac{\partial\psi}{\partial r}\right)dxdy,$$

where ν denotes the direction of the normal to the edge s' drawn outwards. The double integral on the right-hand side contributes a term to the principal equation, and the line integral contributes terms to the boundary conditions. The line integral admits of further transformation by means of the relations

$$\frac{\partial w}{\partial x}=\frac{\partial w}{\partial \nu}\cos(x,\nu)-\frac{\partial w}{\partial s'}\cos(y,\nu),$$

$$\int\cos(x,\nu)\cos(y,\nu)\frac{\partial\psi}{\partial r}\frac{\partial w}{\partial s'}ds'=-\int\frac{\partial}{\partial s'}\left\{\cos(x,\nu)\cos(y,\nu)\frac{\partial\psi}{\partial r}\right\}wds'.$$

It becomes

$$\int \cos^2(x,\nu)\frac{\partial\psi}{\partial r}\frac{\partial w}{\partial \nu}ds'$$
$$+\int\left[\frac{\partial}{\partial s'}\left\{\cos(x,\nu)\cos(y,\nu)\frac{\partial\psi}{\partial r}\right\}-\cos(x,\nu)\frac{\partial}{\partial x}\left(\frac{\partial\psi}{\partial r}\right)\right]wds'.$$

In forming the first term within the square brackets we then use the relations

$$\frac{\partial}{\partial s'}\cos(x,\nu)=-\frac{1}{\rho'}\cos(y,\nu),\ \frac{\partial}{\partial s'}\cos(y,\nu)=\frac{1}{\rho'}\cos(x,\nu),$$
$$\frac{\partial}{\partial s'}\frac{\partial\psi}{\partial r}=-\cos(y,\nu)\frac{\partial}{\partial x}\frac{\partial\psi}{\partial r}+\cos(x,\nu)\frac{\partial}{\partial y}\frac{\partial\psi}{\partial r},$$

where ρ' denotes the radius of curvature of the curve s'.

The necessity of freeing the calculus of variations from dependence upon the notion of infinitely small quantities was realized by Lagrange, and the process of discarding such quantities was partially carried out by him in his *Théorie des fonctions analytiques* (1797). In accordance with the interpretation of differentials which he made in that treatise, he interpreted the variation of an integral, as expressed by means of his symbol δ, as the first term, or the sum of the terms of the first order, in the development in series of the complete expression for the change that is made in the value of the integral when small finite changes are made in the variables. The quantity which had been regarded as the variation of the integral came to be regarded as the first variation, and the discrimination between maxima and minima came to be regarded as requiring the investigation of the second variation. The first step in this theory had been taken by A. M. Legendre in 1786.

The second variation.

In the case of an integral of the form

$$\int_{x_0}^{x_1}F(x,y,y')dx$$

Legendre defined the second variation as the integral

$$\int_{x_0}^{x_1}\frac{1}{2}\left\{\frac{\partial^2F}{\partial y^2}(\delta y)^2+2\frac{\partial^2F}{\partial y\partial y'}\delta y\delta y'+\frac{\partial^2F}{\partial y'^2}(\delta y')^2\right\}dx.$$

To this expression he added the term $\left[\frac{1}{2}\alpha(\delta y)^2\right]_{x_0}^{x_1}$, which vanishes identically because δy vanishes at $x=x_0$ and at $x=x_1$. He took α to satisfy the equation

$$\frac{\partial^2F}{\partial y'^2}\left(\frac{\partial^2F}{\partial y^2}+\frac{d\alpha}{dx}\right)=\left(\frac{\partial^2F}{\partial y\partial y'}+\alpha\right)^2;$$

and thus transformed the expression for the second variation to

$$\int_{x_0}^{x_1}\frac{\partial^2F}{\partial y'^2}(\delta y'+m\delta y)^2dx,$$

where

$$m\frac{\partial^2F}{\partial y'^2}=\frac{\partial^2F}{\partial y\partial y'}+\alpha.$$

From this investigation Legendre deduced a new condition for the existence of an extremum. It is necessary, not only that the variation should vanish, but also that the second variation should be one-signed. In the case of the First Problem Legendre concluded that this cannot happen unless $\partial^2F/\partial y'^2$ has the same sign at all points of the stationary curve between the end points, and that the sign must be + for a minimum and − for a maximum. In the application of the perametric method the function which has been denoted by f_1 takes the place of $\partial^2F/\partial y'^2$.

Legendre's condition.

The transformation of the second variations of integrals of various types into forms in which their signs can be determined by inspection subsequently became one of the leading problems of the calculus of variations. This result came about chiefly through the publication in 1837 of a memoir by C. G. J. Jacobi. He transformed Legendre's equation for the auxiliary function α into a linear differential equation of the second order by the substitution

Jacobi.

$$\frac{\partial^2F}{\partial y\partial y'}+\alpha=-\frac{\partial^2F}{\partial y'^2}\frac{1}{w}\frac{dw}{dx},$$

and he pointed out that Legendre's transformation of the second variation cannot be effected if the function w vanishes between the limits of integration. He pointed out further, that if the stationary curves of the integral are given by an equation of the form

$$y=\phi(x,a,b),$$

where a, b are arbitrary constants, the complete primitive of the equation for w is of the form

$$w=A\frac{\partial\phi}{\partial a}+B\frac{\partial\phi}{\partial b},$$

where A, B are new arbitrary constants. Jacobi stated these propositions without proof, and the proof of them, and the extension of the results to more general problems, became the object of numerous investigations. These investigations were, for the most part, and for a long time, occupied almost exclusively with analytical developments; and the geometrical interpretation which Jacobi had given, and which he afterwards emphasized in his *Vorlesungen über Dynamik*, was neglected until rather recent times. According to this interpretation, the stationary curves which start from a point (x_0, y_0) have an envelope; and the integral of F, taken along such a curve, cannot be an extremum if the point (ξ_0, η_0) where the curve touches the envelope lies on the arc between the end points. Pairs of points such as (x_0, y_0) and (ξ_0, η_0) were afterwards called *conjugate points* by Weierstrass. The proof that the integral cannot be an extremum if the arc of the curve between the fixed end points contains a pair of conjugate points was first published by G. Erdmann (1878).

Conjugate points.

Examples of conjugate points are afforded by antipodal points on a sphere, the conjugate foci of geometrical optics, the kinetic foci of analytical dynamics. If the terminal points are a pair of conjugate points, the integral is not in general an extremum; but there is an exceptional case, of which a suitably chosen arc of the equator of an oblate spheroid may serve as an example. In the problem of the catenoid a pair of conjugate points on any of the catenaries, which are the stationary curves of the problem, is such that the tangents to the catenary at the two points A and A′ meet on the axis of revolution (fig. 2). When both the end points of the required curve move on fixed guiding curves C_0, C_1, a stationary curve C, joining a point A_0 of C_0 to a point A_1 of C_1, cannot yield an extremum unless it is cut transversely by C_0 at A_0 and by C_1 at A_1. The envelope of stationary curves which set out from C_0 towards C_1, and are cut transversely by C_0 at points near A_0, meets C at a point D_0; and the envelope of stationary curves which proceed from C_0 to C_1, and are cut transversely by C_1 at points near A_1, meets C at a point D_1. The curve C, drawn from A_0 to A_1, cannot yield an extremum if D_0 or D_1 lies between A_0 and A_1, or if D_0 lies between A_1 and D_1. These results are due to G. A. Bliss (1903). A simple example is afforded by the shortest line on a sphere drawn from one small circle to another. In fig. 3 D_0 is that pole of the small circle A_0B_0 which occurs first on great circles cutting A_0B_0 at right angles, and proceeding towards A_1B_1; D_1 is that pole of the small circle A_1B_1 which occurs first on great circles cutting A_1B_1 at right angles, and drawn from points of A_0B_0 towards A_1B_1. The arc A_0A_1 is the required shortest line, and it is distinguished from B_0B_1 by the above criterion.

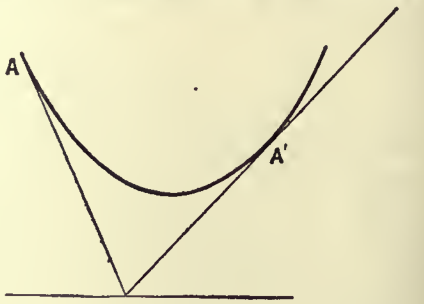

FIG. 2.

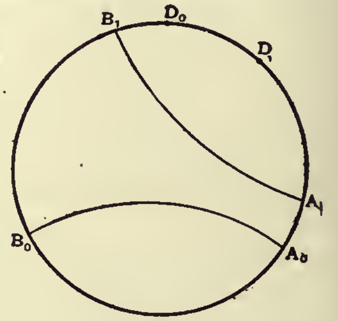

FIG. 3.

Jacobi's introduction of conjugate points is one of the germs from which the modern theory of the calculus of variations has sprung. Another is a remark made by Legendre (1786) in regard to the solution of Newton's problem of the solid of least resistance. This problem requires that a curve be found for which the integral

Sources of Weierstrass's theory.

$$\int yy'^2(1+y'^2)^{-1}dy$$

should be a minimum. The stationary curves are given by the equation

$$yy'^3(1+y'^2)^{-2}=\text{const.},$$

a result equivalent to Newton's solution of the problem; but Legendre observed that, if the integral is taken along a broken line, consisting of two straight lines equally inclined to the axis of x in opposite senses, the integral can be made as small as we please by sufficiently diminishing the angle of inclination. Legendre's remark amounts to admitting a variation of Newton's curve, which is not a weak variation. Variations which are not weak are such that, while the points of a curve are but slightly displaced, the tangents undergo large changes of direction. They are distinguished as *strong variations.* A general theory of strong variations in connexion with the First Problem, and of the conditions which are sufficient to secure that the integral taken along a stationary curve may be an extremum, was given by Weierstrass in lectures. He delivered courses of lectures on the calculus of variations in several years between 1865 and 1889, and his chief discoveries in the subject seem to have been included in the course for 1879. Through these lectures his theory became known to some students and teachers in Europe and America, and there have been published a few treatises and memoirs devoted to the exposition of his ideas.

In the First Problem the following conditions are known to be necessary for an extremum. I. The path of integration must be a stationary curve. II. The expression $\partial^2F/\partial y'^2$, or the expression denoted by f_1 in the application of the parametric method, must not change sign at any point of this curve between the end points. III. The arc of the curve between the end points must not contain a pair of conjugate points. All these results are obtained by using weak variations. Additional

Necessary conditions.

results, relating to strong as well as weak variations, are obtained by a method which permits of the expression of the variation of an integral as a line integral taken along the varied curve. Let A, B be the end points, and let the stationary curve AB be drawn. If the end points A, B are not a pair of conjugate points, and if the point conjugate to A does not lie on the arc AB, then we may find a point A′, on the backward continuation of the stationary curve BA beyond A, so near to A that the point conjugate to A′ lies on the forward continuation of the arc AB beyond B. This being the case, it is possible to delimit an area of finite breadth, so that the arc AB of the stationary curve joining A, B lies entirely within the area, and no two stationary curves drawn through A′ intersect within the area. Through any point of such an area it is possible to draw one, and only one, stationary curve which passes through A′. This family of stationary curves is said to constitute a *field* of stationary curves about the curve AB. We suppose that such a field exists, and that the varied curve AQPB lies entirely within the delimited area. The variation of the integral $\int F(x, y, y')dx$ is identical with the line integral of F taken round a contour consisting of the varied curve AQPB and the stationary curve AB, in the sense AQPBA. The line integral may, as usual, be replaced by the sum of line integrals taken round a series of cells, the external boundaries of the set of cells being identical with the given contour, and the internal boundaries of adjacent cells being traversed twice in opposite senses. We may choose a suitable set of cells as follows. Let Q, P be points on the varied curve, and let A′Q, A′P be the stationary curves of the field which pass through Q, P. Let P follow Q in the sense AQPB in which the varied curve is described. Then the contour consisting of the stationary curve A′Q, from A′ to Q, the varied curve QP, from Q to P, and the stationary curve A′P, from P to A′, is the boundary of a cell (fig. 4). Let us denote the integral of F taken along a stationary curve by round brackets, thus (A′Q), and the integral of F taken along any other curve by square brackets, thus [PQ]. If the varied curve is divided into a number of arcs such as QP we have the result

Field of stationary curves.

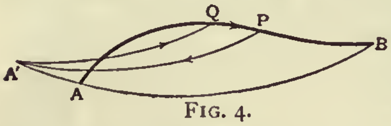

FIG. 4.

General expression for variation of an integral.

$$[AQPB]-(AB)=\Sigma\{(A'Q)+[QP]-(A'P)\},$$

and the right-hand member can be expressed as a line integral taken along the varied curve AQPB.

To effect this transformation we seek an approximate expression for the term $(A'Q)+[QP]-(A'P)$ when Q, P are near together. Let Δs denote the arc QP, and ψ the angle which the tangent at P to the varied curve, in the sense from A to B, makes with the axis of x (fig. 5). Also let ϕ be the angle which the tangent at P to the stationary curve A′P, in the sense from A′ to P, makes with the axis of x. We evaluate $(A'Q)-(A'P)$ approximately by means of a result which we obtained in connexion with the problem of variable limits. Observing that the angle here denoted by ψ is equivalent to the angle formerly denoted by $\pi+\omega$ (cf. fig. 1), while $\tan\phi$ is equivalent to the quantity formerly denoted by y', we obtain the approximate equation

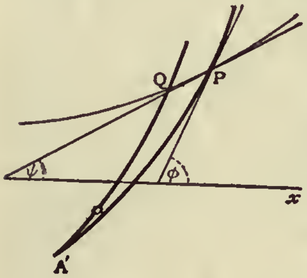

FIG. 5.

$$(A'Q)-(A'P)=-\Delta s.\cos\psi\left\{F(x,y,p)+(\tan\psi-p)\frac{\partial F}{\partial p}\right\}_{p=\tan\phi}$$

which is correct to the first order in Δs. Also we have

$$[QP]=\Delta s\,.\,\cos\psi F(x,y,\tan\psi)$$

correctly to the same order. Hence we find that, correctly to the first order in Δs,

$$(A'Q)+[QP]-(A'P)=E(x,y,\tan\phi,\tan\psi)\Delta s,$$

where

$$E(x,y,\tan\phi,\tan\psi)$$
$$=\cos\psi\left\{F(x,y,\tan\psi)-F(x,y,p)-(\tan\psi-p)\frac{\partial F}{\partial p}\right\}_{p=\tan\phi}.$$

When the parametric method is used the function E takes the form

$$\left(\lambda\frac{\partial f}{\partial \dot{x}}+\mu\frac{\partial f}{\partial \dot{y}}\right)_{\dot{x}=\lambda,\,\dot{y}=\mu}-\left(\lambda\frac{\partial f}{\partial \dot{x}}+\mu\frac{\partial f}{\partial \dot{y}}\right)_{\dot{x}=l,\,\dot{y}=m}$$

where λ, μ are the direction cosines of the tangent at P to the curve AQPB, in the sense from A to B, and l, m are the direction cosines of the tangent at P to the stationary curve A′P, in the sense from A′ to P.

The function E, here introduced, has been called Weierstrass's *excess function*. We learn that the variation of the integral, that is to say, the excess of the integral of F taken along the varied curve above the integral of F taken along the original curve, is expressible as the line integral $\int E ds$ taken along the varied curve. We can therefore state a *sufficient* (but not necessary) condition for the existence of an extremum in the form:—When the integral is taken along a stationary curve, and there is no pair of conjugate points on the arc of the curve terminated by the given end points, the integral is certainly an extremum if the excess function has the same sign at all points of a finite area containing the whole of this arc within it. Further, we may specialize the excess function by identifying A′ with A, and calculating the function for a point P on the arc AB of the stationary curve AB, and an arbitrary direction of the tangent at P to the varied curve. This process is equivalent to the introduction of a particular type of strong variation. We may in fact take, as a varied curve, the arc AQ of a neighbouring stationary curve, the straight line QP drawn from Q to a point of the arc AB, and the arc PB of the stationary curve AB (fig. 6). The sign of the variation is then the same as that of the function $E(x, y, \tan\phi, \tan\psi)$, where (x, y) is the point P, ψ is the angle which the straight line QP makes with the axis of x, and ϕ is the angle which the tangent at P to the curve APB makes with the same axis. We thus arrive at a new *necessary* (but not sufficient) condition for the existence of an extremum of the integral $\int F ds$, viz. the specialized excess function, so calculated, must not change sign between A and B.

Weierstrass's excess function.

Sufficient and necessary conditions.

FIG. 6.

The sufficient condition, and the new necessary condition, associated with the excess function, as well as the expression for the variation as $\int E ds$, are due to Weierstrass. In applications to special problems it is generally permissible to identify A′ with A, and to regard QP as straight. The direction of QP must be such that the integral of F taken along it is finite and real. We shall describe such directions as *admissible*. In the statement of the sufficient condition, and the new necessary condition, it is of course understood that the direction specified by ψ is admissible. The excess function generally vanishes if $\psi=\phi$, but it does not change sign. It can be shown without difficulty that, when ψ is very nearly equal to ϕ, the sign of E is the same as that of

Developments connected with the excess function.

$$(\tan\psi-\tan\phi)^2\cos\phi\left(\frac{\partial^2 F}{\partial y'^2}\right)_{y'=\tan\phi}$$

and thus the necessary condition as to the sign of the excess function includes Legendre's condition as to the sign of $\partial^2F/\partial y'^2$.

Weierstrass's conditions have been obtained by D. Hilbert from the observation that, if p is a function of x and y, the integral

$$\int\left\{F(x,y,p)+(y'-p)\left(\frac{\partial F}{\partial y'}\right)_{y'=p}\right\}dx,$$

taken along a curve joining two fixed points, has the same value for all such curves, provided that there is a field of stationary curves, and that p is the gradient at the point (x, y) of that stationary curve of the field which passes through this point.

An instructive example of the excess function, and the conditions connected with it, is afforded by the integral

$$\int y^2y'^{-2}dx \text{ or } \int y^2\dot{x}^3\dot{y}^{-2}d\theta.$$

Example of the excess function.

The first integral of the principal equation is

$$y^2\dot{x}^2\dot{y}^{-2}=\text{const.},$$

and the stationary curves include the axis of x, straight lines parallel to the axis of y, and the family of exponential curves $y=ae^{cx}$. A field of stationary curves is expressed by the equation

$$y=y_0\exp\{c(x-x_0)\},$$

and, as these have no envelope other than the initial point (x_0, y_0), there are no conjugate points. The function f_1 is $6\dot{x}\dot{y}^{-4}$, and this is positive for curves going from the initial point in the positive direction of the axis of x. The value of the excess function is

$$y^2\cos\psi(\cot^2\psi-3\cot^2\phi+2\tan\psi\cot^3\phi).$$

The directions $\psi=0$ and $\psi=\pi$ are inadmissible. On putting $\psi=\frac{1}{2}\pi$ we get $2y^2\cot^3\phi$; and on putting $\psi=\frac{3}{2}\pi$ we get $-2y^2\cot^3\phi$. Hence the integral taken along AQ′PB is greater than that taken along APB, and the integral taken along AQPB is less than that taken along APB, when Q′Q are sufficiently near to P on the ordinate of P (fig. 7). It follows that the integral is neither a maximum nor a minimum.

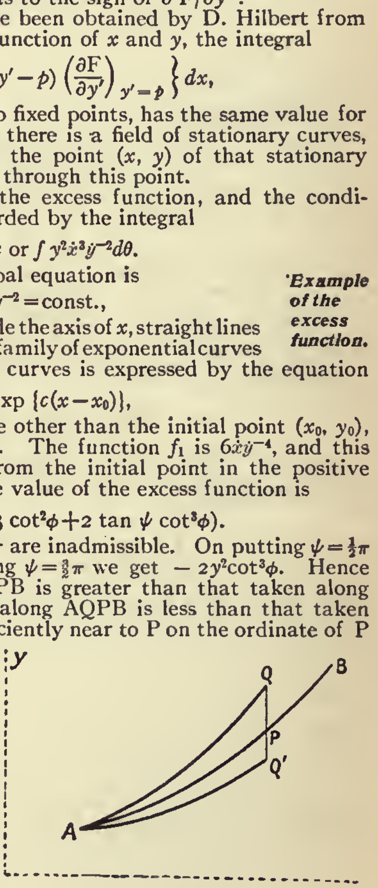

FIG. 7.

It has been proved by Weierstrass that the excess function cannot be one-signed if the function f of the parametric method is a rational function of $\dot{x}$ and $\dot{y}$. This result includes the above example, and the problem of the solid of least resistance, for which, as Legendre had seen, there can be no solution if strong variations are admitted. As another example of the calculation of excess functions, it may be noted that the value of the excess function in the problem of the catenoid is $2y\sin^2\frac{1}{2}(\psi-\phi)$.

In general it is not necessary that a field of stationary curves should consist of curves which pass through a fixed point. Any family of stationary curves depending on a single parameter may constitute a field. This remark is of importance in connexion with the adaptation of Weierstrass's results to the problem of variable limits. For the purpose of this adaptation A. Kneser (1900) introduced the family of stationary curves which are cut transversely by an assigned curve. Within the field of these curves we can construct the transversals of the family; that is to say, there is a finite area of the plane, through any point of which there passes one stationary curve of the field and one curve which cuts all the stationary curves of the field transversely. These curves provide a system of curvilinear co-ordinates, in terms of which the value of $\int Fdx$, taken along any curve within the area, can be expressed. The value of the integral is the same for all arcs of stationary curves of the field which are intercepted between any two assigned transversals.

Field of stationary curves and transversals.

In the above discussion of the First Problem it has been assumed that the curve which yields an extremum is an arc of a single curve, which must be a stationary curve. It is conceivable that the required curve might be made up of a finite number of arcs of different stationary curves meeting each other at finite angles. It can be shown that such a broken curve cannot yield an extremum unless both the expressions $\partial F/\partial y'$ and $F - y'(\partial F/\partial y')$ are continuous at the corners. In the parametric method $\partial f/\partial \dot{x}$ and $\partial f/\partial \dot{y}$ must be continuous at the corners. This result limits very considerably the possibility of such discontinuous solutions, though it does not exclude them. An example is afforded by the problem of the catenoid. The axis of x and any lines parallel to the axis of y satisfy the principal equation; and the conditions here stated show that the only discontinuous solution of the problem is presented by the broken line ACDB (fig. 8). A broken line like AA'B'B is excluded. Discontinuous solutions have generally been supposed to be of special importance in cases where the required curve is restricted by the condition of not crossing the boundary of a certain limited area. In such cases part of the boundary may have to be taken as part of the curve. Problems of this kind were investigated in detail by J. Steiner and I. Todhunter. In recent times the theory has been much extended by C. Carathéodory.

Discontinuous solutions.

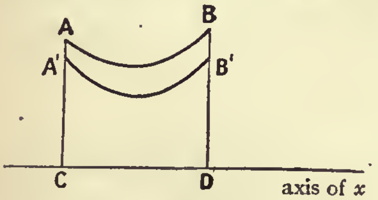

FIG. 8.

In any problem of the calculus of variations the first step is the formation of the principal equation or equations; and the second step is the solution of the equation or equations, in accordance with the assigned terminal or boundary conditions. If this solution cannot be effected, the methods of the calculus fail to answer the question of the existence or non-existence of a solution which would yield a maximum or minimum of the integral under consideration. On the other hand, if the existence of the extremum could be established independently, the existence of a solution of the principal equation, which would also satisfy the boundary conditions, would be proved. The most famous example of such an existence-theorem is Dirichlet's principle, according to which there exists a function V, which satisfies the equation

Existence-theorems.

$$\frac{\partial^2 V}{\partial x^2}+\frac{\partial^2 V}{\partial y^2}+\frac{\partial^2 V}{\partial z^2}=0$$

at all points within a closed surface S, and assumes a given value at each point of S. The differential equation is the principal equation answering to the integral

$$I=\iiint\left\{\left(\frac{\partial V}{\partial x}\right)^2+\left(\frac{\partial V}{\partial y}\right)^2+\left(\frac{\partial V}{\partial z}\right)^2\right\}dx\,dy\,dz$$

taken through the volume within the surface S. The theorem of the existence of V is of importance in all those branches of mathematical physics in which use is made of a potential function, satisfying Laplace's equation; and the two-dimensional form of the theorem is of fundamental importance in the theory of functions of a complex variable. It has been proposed to establish the existence of V by means of the argument that, since I cannot be negative, there must be, among the functions which have the prescribed boundary values, some one which gives to I the smallest possible value. This unsound argument was first exposed by Weierstrass. He observed that precisely the same argument would apply to the integral $\int x^2y'^2dx$ taken along a curve from the point $(-1, a)$ to the point $(1, b)$. On the one hand, the principal equation answering to this integral can be solved, and it can be proved that it cannot be satisfied by any function y at all points of the interval $-1<x<1$ if y has different values at the end points. On the other hand, the integral can be made as small as we please by a suitable choice of y. Thus the argument fails to distinguish between a *minimum* and an *inferior limit* (see FUNCTION). In order to prove Dirichlet's principle it becomes necessary to devise a proof that, in the case of the integral I, there cannot be a limit of this kind. This has been effected by Hilbert for the two-dimensional form of the problem.

Dirichlet's principle.

BIBLIOGRAPHY.—The literature of the subject is very extensive, and only a few of the more important works can be cited here. The earlier history can be gathered from M. Cantor's *Geschichte d. Math.* Bde. 1–3 (Leipzig, 1894–1901). I. Todhunter's *History of the Calculus of Variations* (London, 1861) gives an account of the various treatises and memoirs published between 1760 and 1860. E. Pascal's *Calcolo delle variazioni* . . . (Milan, 1897; German translation, Leipzig, 1899) contains a brief but admirable historical summary of the pre-Weierstrassian theory with references to the literature. A general account of the subject, including Weierstrass's theory, is given by A. Kneser, *Ency. d. math. Wiss.* ii. A 8; and an account of various extensions of Weierstrass's theory and of Hilbert's work is given by E. Zermelo and H. Hahn, *Ency. d. math. Wiss.* ii. A 8a (Leipzig, 1904). The following treatises may be mentioned: L. Euler, *Methodus inveniendi lineas curvas maximi minimive proprietate gaudentes* . . . (Lausanne and Geneva, 1744); J. H. Jellett, *An Elementary Treatise on the Calculus of Variations* (Dublin, 1850); E. Moigno and L. Lindelöf, "Leçons sur le calc. diff. et int.," *Calcul des variations* (Paris, 1861), t. iv.; L. B. Carll, *A Treatise on the Calculus of Variations* (London, 1885). E. Pascal's book cited above contains a brief systematic treatise on the simpler parts of the subject. A. Kneser, *Lehrbuch d. Variationsrechnung* (Brunswick, 1900); H. Hancock, *Lectures on the Calculus of Variations* (Cincinnati, 1904); and O. Bolza, *Lectures on the Calculus of Variations* (Chicago, 1904), give accounts of Weierstrass's theory. Kneser has made various extensions of this theory. Bolza gives an introduction to Hilbert's theories also. The following memoirs and monographs may be mentioned: J. L. Lagrange, "Essai sur une nouvelle méthode pour déterminer les max. et les min. des formules intégrales indéfinies," *Misc. Taur.* (1760–62), t. ii., or *Œuvres*, t. i. (Paris, 1867); A. M. Legendre, "Sur la manière de distinguer les max. des min. dans le calc. des var.," *Mém. Paris Acad.* (1786); C. G. J. Jacobi, "Zur Theorie d. Variationsrechnung . . . ," *J. f. Math.* (Crelle), Bd. xvii. (1837), or *Werke*, Bd. iv. (Berlin, 1886); M. Ostrogradsky, "Mém. sur le calc. des var. des intégrales multiples," *Mém. St Pétersburg Acad.* (1838); J. Steiner, "Einfache Beweise d. isoperimetrischen Hauptsätze," *J. f. Math.* (Crelle), Bd. xviii. (1839); O. Hesse, "Über d. Kriterien d. Max. u. Min. d. einfachen Integrale," *J. f. Math.* (Crelle), Bd. liv. (1857); A. Clebsch, "Über diejenigen Probleme d. Variationsrechnung welche nur eine unabhängige Variable enthalten," *J. f. Math.* (Crelle), Bd. lv. (1858), and other memoirs in this volume and in Bd. lvi. (1859); A. Mayer, *Beiträge z. Theorie d. Max. u. Min. einfacher Integrale* (Leipzig, 1866), and "Kriterien d. Max. u. Min. . . ," *J. f. Math.* (Crelle), Bd. lxix. (1868); I. Todhunter, *Researches in the Calc. of Var.* (London, 1871); G. Sabinine, "Sur . . . les max . . . des intégrales multiples," *Bull. St Pétersburg Acad.* (1870), t. xv., and "Développements . . . pour . . . la discussion de la variation seconde des intégrales . . . multiples," *Bull. d. sciences math.* (1878); G. Frobenius, "Über adjungirte lineare Differentialausdrücke," *J. f. Math.* (Crelle), Bd. lxxxv. (1878); G. Erdmann, "Zur Untersuchung d. zweiten Variation einfacher Integrale," *Zeitschr. Math. u. Phys.* (1878), Bd. xxiii.; P. Du Bois-Reymond, "Erläuterungen z. d. Anfangsgründen d. Variationsrechnung," *Math. Ann.* (1879), Bd. xv.; L. Scheeffer, "Max. u. Min. d einfachen Int.," *Math. Ann.* (1885), Bd. xxv., and "Über d. Bedeutung d. Begriffe Max . . . ," *Math. Ann.* (1886), Bd. xxvi.; A. Hirsch, "Über e. charakteristische Eigenschaft d. Diff.-Gleichungen d. Variationsrechnung," *Math. Ann.* (1897), Bd. xlix. The following deal with Weierstrassian and other modern developments: H. A. Schwarz, "Über ein die Flächen kleinsten Flächeninhalts betreffendes Problem d. Variationsrechnung," Festschrift on the occasion of Weierstrass's 70th birthday (1885), *Werke*, Bd. i. (Berlin, 1890); G. Kobb, "Sur les max. et les min. des int. doubles," *Acta Math.* (1892–93), Bde. xvi., xvii.; E. Zermelo. "Untersuchungen z. Variationsrechnung," *Dissertation* (Berlin, 1894); W. F. Osgood, "Sufficient Conditions in the Calc. of Var.," *Annals of Math.* (1901), vol. ii., also, "On the Existence of a Minimum . . . ," and "On a Fundamental Property of a Minimum . . . ," *Amer. Math. Soc. Trans.* (1901), vol. ii.; D. Hilbert, "Math. Probleme," *Göttingen Nachr.* (1900), and "Über das Dirichlet'sche Prinzip," *Göttingen Festschr.* (Berlin, 1901); G. A. Bliss, "Jacobi's Criterion when both End Points are variable," *Math. Ann.* (1903), Bd. lviii.; C. Carathéodory, "Über d. diskontinuirlichen Lösungen i. d. Variationsrechnung," *Dissertation* (Göttingen, 1904); and "Über d. starken Max . . . ," *Math. Ann.* (1906), Bd. lxii. (A. E. H. L.)

VARICOSE VEINS (Lat. *varix*, a dilated vein), a condition of the veins which mostly occurs in those parts of the blood-stream which are farthest from the heart and occupy a dependent position. Thus they are found in the legs and thighs; in the lowest part of the bowel (piles; see HAEMORRHOIDS), and in the spermatic cord (varicocele). Any condition which hinders the return of blood from the veins is apt to cause their permanent dilatation; thus is explained the occurrence of varicose veins in the leg from the wearing of a tight garter, and of piles as the result of the pressure of an ovarian tumour or of a pregnant uterus, or of disease of the liver.

Sometimes the trouble is begun by a direct injury to the vein, which, by setting up an inflammation, weakens the coats of the vein, which then yield under the pressure of the blood-stream. In the case of varicocele, the dilatation of the veins is probably of developmental origin; many other causes are given, but not one of them appears satisfactory. Examination of a varicose vein shows that it is increased in length as well as in capacity. In some parts of its course the vein has its coats much thickened, but at those places where there is most dilatation the walls are very thin. Veins thus affected give rise to pains and achings, and they are, moreover, liable to attacks of inflammation which end in clotting of the blood (*thrombosis*). This is a dangerous condition, as a sudden or violent movement is apt to cause the detachment of a piece of the clot, which, carried up to the brain or the lung, may cause sudden death. Less serious results of varicose veins are swelling of the parts below (*oedema*), ulceration and abscess.

As regards treatment, the wearing of a well-fitting elastic stocking will prove beneficial in the case of a moderate dilatation of the veins of the leg; the individual must avoid long standing and fatigue. It is well also to have the foot of the bed raised three or four inches, so that during the night the veins may be kept as empty as possible. If the case is more serious, the thinned veins threatening to give way, it will be advisable, provided the dilatations are fairly well localized, and the general condition of the patient permits, to excise the diseased parts, tying the cut ends of the veins, and closing the surface wounds with fine sutures. Should a varicose vein be plugged with clot, it will be advisable to tie it high up where the coats are healthy, and to remove the lower part by dissection. This will render the person safe from the very serious risk of a piece of the clot being carried to the heart, and will also permanently rid him of his trouble. It may be said generally that any operative treatment for varicose veins in the lower extremity is best associated with the application of a ligature upon the large surface vein just before it enters the common femoral vein below the fold of the groin. This operation removes the risk of the downward pressure of blood in the veins whose dilatation has rendered the valves useless.

In the case of a varicose vein being opened by accident or disease, it is quite possible for the individual to bleed to death. The first-aid treatment for the serious haemorrhage should consist in laying the patient on the floor, raising the limb upon the seat of a chair, and fixing a pad over the open vessel by a handkerchief or bandage.

Varicose veins of the spermatic cord (*varicocele*) of the left side are met with in adolescents. The dilatation is, in all probability, of developmental origin, making its appearance at puberty. It is, as a rule, of no serious moment, and, unless present in an extreme degree, had best be treated merely by a suspension bandage. If, however, it is causing real physical distress, it may be treated by excision of an inch or two of the bunch of dilated veins. The presence of varicocele is apt to cause inconvenience or even discomfort to men living in India or the tropics, but the Englishman who intends spending his life in temperate climes will do well to ignore a varicocele. It will become less and less noticeable as time goes on. (E. O.*)

VARIOLITES (Lat. *variola*, smallpox), in petrology, a group of dark green basic igneous rocks which, especially on weathered surfaces, exhibit pale coloured spots that give them a pock-marked appearance. In some conditions these spots weather out prominently; they are grey, pale green, violet or yellowish, while the matrix of the rock is usually dark green. The variolites are related most closely to the basalts or diabases. They are nearly always much decomposed, and, since they are also fine-grained rocks, their original composition may be much obscured by secondary changes. The variolitic spots are rounded in outline and are often about a quarter of an inch in diameter, but may much exceed this size. They have a radiate structure and are sometimes, though not generally, zoned with concentric circles of different appearance and composition. Many authors have compared them with the spherulites of the acid rocks (obsidians and rhyolites), and undoubtedly some kinds of variolite are merely glassy spherulitic varieties of basalt. The tachylyte selvages of the dolerite dikes of the west of Scotland, for example, often contain large brown spherulites which are easily visible in hand specimens. These spherulites consist of very thin divergent fibres, and their nature is often difficult to determine on account of the indefiniteness of the optical characters of minerals in this state. It seems probable, however, that they are mostly felspar embedded in dark brown glass. Small phenocrysts or skeleton crystals of olivine, augite and plagioclase felspar may occur in these tachylytes.

Other variolites are glassy or partly crystalline facies of olivine-free dolerites, occurring as thin dikes or intrusions, or at the margins of dolerite masses. In these the felspars are well crystallized as thin rods, with square or forked ends, radiating outwards from a centre. They are commonly oligoclase, and sometimes assume branching or feathery forms. Some authors would call these "sphaero-crystals" rather than spherulites; they are an intermediate stage between the latter and the stellate groupings of felspar which occur frequently in igneous rocks. In the same rocks augite spherulites occur also, but this mineral forms plumose growths, branching and curved, which spread through the glassy base and do not interfere with the felspar spherulites. They have much resemblance to the feathery ice crystals which form on window-panes. Occasionally olivine-dolerites have a coarsely spherulitic structure with long rods of plagioclase felspar converging to a point; one example of these rocks from Skye contains variolites over three inches in diameter.

Another group of variolites includes the most famous rock of this type, which comes from the Durance, in France. Pebbles of this were well known to collectors for a long time before they were traced to their source at Mont Genèvre. They were proved to belong to a diabasic rock which shows well-marked "pillow-structure" or "spheroidal jointing." Each pillow has a marginal portion which is variolitic, but towards the centre of the block-shaped masses the structure becomes coarse and groups of radiate felspars make their appearance. It is doubtful whether the variolite is an intrusive rock or a lava flow. Many of these pillow lavas (or spilites) occur in the Devonian rocks of Germany, and often they have variolitic facies which seem to belong to the same group as the rock of the Durance. Their spherulites are very often oligoclase felspar or decomposition products after a felspathic mineral. In other cases they consist of chlorite or pale green amphibole, both of which may be secondary after pyroxene. The ground mass is very fine grained and is filled with chlorite, epidote, leucoxene, and other secondary minerals. There is much reason to believe that it was originally in large measure vitreous but has suffered devitrifaction. Sometimes little steam cavities occur and may serve as a nucleus from which the variolite has grown. The radiate structure of the varioles is often nearly obliterated in these much-decomposed rocks, in fact it may never have been very perfect. Variolites are found also in several parts of the Swiss Alps at Jatluga on Lake Onega, in Anglesey, the Lleyn district and Fishguard in Wales, in Cornwall, and in more than one place in Ireland.

Finally, there is a group of spotted rocks formerly known to French petrographers as the *variolites du Drac* from the locality in which they are found, but they have been proved to be merely vesicular, rotten diabases, with steam cavities filled with white calcite and other secondary minerals. (J. S. F.)

VARISCITE, a native hydrous aluminium phosphate, $AlPO_4 \cdot 2H_2O$, named by A. Breithaupt, in 1837, in consequence of its occurrence in the Saxon Voigtland (Variscia). It is a green mineral generally occurring as an incrustation or in nodules. A compact nodular variety was discovered about 1894 in Cedar Valley, near Old Camp Floyd, Utah, and was described by Dr G. F. Kunz as utahlite. Its beautiful apple-green colour has led to its use, when cut and polished, as an ornamental stone. The term utahlite must be distinguished from utahite, the name given by A. Arzruni to a basic ferric sulphate, $3(FeO)_2SO_4 \cdot 4H_2O$, from Utah.

VARLEY, CORNELIUS (1781–1873), English water-colour painter, a younger brother of John Varley (*q.v.*), was born at Hackney, London, on the 21st of November 1781. He was educated by his uncle, a philosophical instrument maker, and under him acquired a knowledge of the natural sciences; but about 1800 he joined his brother in a tour through Wales, and began the study of art. He was soon engaged in teaching drawing. From 1803 till 1859 he was an occasional exhibitor in the Royal Academy; and he also contributed regularly to the displays of the Water-Colour Society, of which, in 1803, he was one of the founders, and of which he continued a member till 1821. His works consist mainly of carefully finished classical subjects, with architecture and figures. He published a series of etchings of "Boats and other Craft on the River Thames," and during his life as an artist he continued deeply interested in scientific pursuits. For his improvements in the camera lucida, the camera obscura and the microscope he received the Isis gold medal of the Society of Arts; and at the International

Exhibition of 1851 he gained a medal for his invention of the graphic telescope. He died at Hampstead on the 2nd of October 1873.

VARLEY, JOHN (1778–1842), English water-colour painter, was born at Hackney, London, on the 17th of August 1778. His father, a man of scientific attainments and tutor in the family of Lord Stanhope, discouraged his leanings towards art, and placed him under a silversmith. But on his parent's death Varley escaped from this uncongenial employment, and, after working with a portrait painter, engaged himself at the age of sixteen to an architectural draughtsman, who took him on a provincial tour to sketch the principal buildings in the towns they visited. His spare hours were employed in sketching from nature, and in the evenings he was permitted, like Turner and Girtin, to study in the house of Dr Munro. In 1798 he exhibited his first work, a "View of Peterborough Cathedral," in the Royal Academy. In 1799 he visited North Wales, and in its wild mountain scenery found the subjects best suited to his brush. He returned to the same district in 1800, and again in 1802, and the impressions then received powerfully influenced the whole course of his art. In 1804 he became a foundation member of the Water-Colour Society, and contributed over forty works to its first exhibition. He had married in the previous year; and, in order to provide for the wants of an increasing family, he was obliged to produce for the dealers much work of a slight and commonplace character. He also taught drawing, and some of his pupils, such as John Linnell and William Hunt, afterwards became celebrated. He was a firm believer in astrology, skilful in casting horoscopes; and some curious instances were related of the truth of his predictions. It was at his house that his friend William Blake sketched his celebrated "Visionary Heads." Varley died at London on the 17th of November 1842.

Varley's landscapes are graceful and solemn in feeling, and simple and broad in treatment, being worked with a full brush and pure fresh transparent tints, usually without any admixture of body-colour. Though his works are rather mannered and conventional, they are well considered and excellent in composition. Some of his earlier water-colours, including his "Views of the Thames," were painted upon the spot, and possess greater individuality than his later productions, which are mainly compositions of mountain and lake scenery, produced without direct reference to nature. Among his literary works are *Zodiacal Physiology* (1828); *Observations on Colour and Sketching from Nature* (1830); *A Practical Treatise on Perspective, and Principles of Landscape Design for Young Artists.*

VARNA, a fortress, seaport, departmental capital and episcopal city of Bulgaria; on the Bay of Varna, an inlet of the Black Sea, in 43° 12′ N. and 27° 56′ E. Pop. (1906) 37,155. Varna is built on the hilly north shore of the bay, overlooking the estuary of the river Devna or Pravadi, which flows seaward through a magnificent valley surrounded by mountains. It is the eastern terminus of the Varna-Rustchuk railway, opened in 1867, and is connected with all parts of the kingdom by branches of this line. The so-called "Varna quadrilateral," which has played an important part in Bulgarian military history, consists of the fortresses of Varna, Shumla, Rustchuk and Silistria (*q.v.*). Varna is the third city of the kingdom in population, after Sofia and Philippopolis, and ranks with Burgas as one of the two principal seaports. Its deep and capacious bay is sheltered from northerly and north-easterly winds, and the construction of modern harbour works has greatly increased the facilities for trade. The principal exports a e cattle and dairy produce, grain, lamb and goat skins, and cloth (*shayak*); the imports include coal, iron and machinery, textiles, petroleum and chemicals. In 1907 the port was entered by 869 ships of 926,449 tons, the largest number of vessels being Bulgarian and the greatest tonnage Austro-Hungarian. Wine is largely produced in the department, and in the city there are breweries, distilleries, tanneries and cloth factories; cotton-spinning was introduced by a British firm. There is a large and commercially important colony of Greeks; the Jews, Turks and gipsies are also numerous. Much of the city has been constructed since 1878, and the barracks, post office, college for girls and National Bank are handsome modern buildings. Near Varna is the summer palace of the king of Bulgaria.

Varna has been identified with the ancient Milesian colony of *Odessus* on the coast of Moesia Inferior. It figures largely in the history of more recent times, and close by was fought in 1444 the battle in which Murad II. slew Wladislaus III. of Poland and Hungary, and routed his forces commanded by Hunyadi János. Varna was occupied in 1828 by the Russians, in 1854 by the allies, who here organized the invasion of the Crimea, and in 1877 by the Egyptian troops summoned to the defence of Turkey against the Russians. By the treaty of Berlin (1878) it was ceded to Bulgaria. It has long been the seat of a Greek metropolitan and since 1870 of a Bulgarian bishop.

VARNHAGEN VON ENSE, KARL AUGUST (1785–1858), German biographer, was born at Düsseldorf on the 21st of February 1785. He studied medicine at Berlin, but devoted more attention to philosophy and literature, which he afterwards studied more thoroughly at Halle and Tübingen. He began his literary career in 1804 as joint-editor with Adelbert von Chamisso (*q.v.*) of a *Musenalmanach.* In 1809 he joined the Austrian army, and was wounded at the battle of Wagram. Soon afterwards he accompanied his superior officer, Prince Bentheim, to Paris, where he carried on his studies. In 1812 he entered the Prussian civil service at Berlin, but in the following year resumed his military career, this time as a captain in the Russian army. He accompanied Tettenborn, as adjutant, to Hamburg and Paris, and his experiences were recorded in his *Geschichte der Hamburger Ereignisse* (London, 1813), and his *Geschichte der Kriegszüge des Generals von Tettenborn* (1815). At Paris he entered the diplomatic service of Prussia, and in 1814 acted under Hardenberg at the congress of Vienna. He also accompanied Hardenberg to Paris in 1815. He was resident minister for some time at Karlsruhe, but was recalled in 1819, after which, with the title of "Geheimer Legationsrat," he lived chiefly at Berlin. He had no fixed official appointment, but was often employed in important political business. In 1814 he married Rahel Antonie Friederike, originally called Levin, afterwards Robert, and sister of the poet, Ludwig Robert (1778–1832). She was born in 1771 at Berlin, where she died in 1833. By birth she was a Jewess; but before her marriage she made profession of Christianity. Although she never wrote anything for publication, she was a woman of remarkable intellectual qualities, and exercised a powerful influence on many men of high ability. Her husband, who was devotedly attached to her, found in her sympathy and encouragement one of the chief sources of his inspiration as a writer. After her death he published a selection from her papers, and afterwards much of her correspondence was printed. Varnhagen von Ense never fully recovered from the shock caused by her death. He himself died suddenly in Berlin on the 10th of October 1858.

He made some reputation as an imaginative and critical writer, but he is famous chiefly as a biographer. He possessed a remarkable power of grouping facts so as to bring out their essential significance, and his style is distinguished for its strength, grace and purity. Among his principal works are *Goethe in den Zeugnissen der Mitlebenden* (1824); *Biographische Denkmale* (5 vols., 1824–30; 3rd ed., 1872); and biographies of General von Seydlitz (1834), Sophia Charlotte, queen of Prussia (1837), Field-Marshal Schwerin (1841), Field-Marshal Keith (1844), and General Bülow von Dennewitz (1853). His *Denkwürdigkeiten und vermischte Schriften* appeared in 9 vols. in 1843–59, the two last volumes appearing after his death. His niece, Ludmilla Assing, between 1860 and 1867, edited several volumes of his correspondence with eminent men, and his *Tagebücher* (14 vols., 1861–70). *Blätter aus der preussischen Geschichte* appeared in 5 vols. (1868–69); his correspondence with Rahel in 6 vols. (1874–75); and with Carlyle (1892). His selected writings appeared in 19 vols. in 1871–76. There is also an extensive literature dealing with Rahel Varnhagen von Ense; see especially her husband's *Rahel, ein Buch des Andenkens* (3 vols., 1834); *Aus Rahels Herzensleben* (1877); E. Schmidt-Weissenfels, *Rahel und ihre Zeit* (1857); *Briefwechsel zwischen Karoline von Humboldt, Rahel und Varnhagen von Ense* (1896); O. Berdrow, *Rahel Varnhagen* (1900).

VARNISH, a liquid consisting of a gum or resin dissolved in alcohol (spirit varnish) or an oil (oil varnish), which on application to wooden and other surfaces improves their appearance and permanency (see PAINTER-WORK).

VARRO, MARCUS TERENTIUS (116–27 B.C.), Roman polymath and man of letters, was born at Reate in the Sabine country. Here he imbibed in his earlier years a good measure of the hardy simplicity and strong seriousness which the later Romans attributed to the men of the early republic—characteristics which were supposed to linger in the Sabine land after they had fled from the rest of Italy. The chief teacher of Varro was L. Aelius Stilo, the first systematic student, critic and teacher of Latin philology and literature, and of the antiquities of Rome and Italy. Varro also studied at Athens, especially under the philosopher Antiochus of Ascalon, whose aim it was to lead back the Academic school from the scepticism of Arcesilaus and Carneades to the tenets of the early Platonists, as he understood them. He was really a stoicizing Platonist; and this has led to the error of supposing Varro to have been a professed Stoic. The influence of Antiochus is clearly to be seen in many remains of Varro's writings. The political career of Varro seems to have been late and slow; but he arrived at the praetorship, after having been tribune of the people, quaestor and curule aedile. In politics and war he followed Pompey's lead; but it is probable that he was discontented with the course on which his leader entered when the first triumvirate was formed, and he may thus have lost his chance of rising to the consulate. He actually ridiculed the coalition in a work entitled the *Three-Headed Monster* (Τρικάρανος in the Greek of Appian). He did not, however, refuse to join the commission of twenty by whom the great agrarian scheme of Caesar for the resettlement of Capua and Campania was carried into execution (59 B.C.). Despite the difference between them in politics, Varro and Caesar had literary tastes in common, and were friends in private life. Under Pompey Varro saw much active service: he was attached to Pompey as pro-quaestor, probably during the war against Sertorius in Spain. We next find him, as legate, in command of a fleet which kept the seas between Delos and Sicily, while Pompey was suppressing the pirates, and he even won the "naval crown," a coveted reward of personal prowess. A little later he was legate during the last Mithradatic war. In the conflict between Caesar and the Pompeian party Varro was more than once actively engaged. In his *Civil War* (ii. 17–20) Caesar tells how Varro, when legate in Spain along with Afranius and Petreius, lost his two legions without striking a blow, because the whole region where he was quartered joined the enemy. Caesar curiously intimates that, though Varro did his best for Pompey from a sense of duty, his heart was really with the other leader. Nevertheless he proceeded to Epirus before the battle of Pharsalia, and awaited the result at Dyrrachium in the company of Cicero and Cato. Like Cicero, Varro received harsh treatment from Mark Antony after the Pompeian defeat. Some of his property was actually plundered, but restored at the bidding of Caesar, to whom Varro in gratitude immediately dedicated one of his most important writings. The dictator employed the scholar in aiding him to collect and arrange great stores of Greek and Latin literature for the vast public library which he intended to found. We have glimpses of Varro at this time in the *Letters* of Cicero. He appears as harsh and severe, and a poor stylist. The formation of the second triumvirate again plunged Varro into danger. Antony took possession anew of the property he had been compelled to surrender, and inserted Varro's name on the list of the proscribed. His friends, however, afforded him protection. He was able to make peace with the triumvirs, but sacrificed his property and much of his beloved library. He was permitted to spend in quiet study and in writing the last fifteen years of his life. He is said to have died (27 B.C.) almost pen in hand.

Varro was not surpassed in the compass of his writings by any ancient, not even by any one of the later Greek philosophers, to some of whom tradition ascribes a fabulous number of separate works. In a passage quoted by Gellius, Varro himself, when over seventy years of age, estimated the number of "books" he had written at 490; but "book" here means, not merely such a work as was not subdivided into portions, but also a portion of a subdivided work. For example, the *Menippean Satires* numbered 150, and are all counted separately in Varro's estimate. Jerome made or copied a catalogue of Varro's works which has come down to us in a mutilated form. From this and from other extant materials Ritschl has set down the number of the distinct literary works at 74 and the number of separate "books" at about 620. The later years of the author's life were therefore even more fruitful than the earlier. The complete catalogue may be roughly arranged under three heads—(1) belles lettres, (2) history and antiquities, (3) technical treatises on philosophy, law, grammar, mathematics, philology and other subjects.

The first of these three classes no doubt mainly belonged to Varro's earlier life. In poetry he seems to have attempted nothing that was very elaborate, and little of a serious character. His genius tended naturally in the direction of burlesque and satire. In belles lettres he showed himself throughout, both in matter and form, the pupil and admirer of Lucilius, after whom he wrote satires. One poetical work probably consisted of short pieces in the style of the more satirical poems of Catullus. It is doubtful whether, as has often been supposed, Varro wrote a philosophical poem somewhat in the style of Lucretius; if so, it should rather be classed with the prose technical treatises. One curious production was an essay in popular illustrated literature, which was almost unique in ancient times. Its title was *Imagines*, and it consisted of 700 prose biographies of Greek and Roman celebrities, with a metrical *elogium* for each, accompanied in each case by a portrait. But the lighter works of Varro have perished almost to the last line, with the exception of numerous fragments of the *Menippean Satires*. The Menippus whom Varro imitated lived in the first half of the 3rd century B.C., and was born a Phoenician slave. He became a Cynic philosopher, and is a figure familiar to readers of Lucian. He flouted life and all philosophies but the Cynic in light compositions, partly in prose and partly in verse. A careful study of the fragments does not justify Mommsen's glowing account. That the remains exhibit variety and fertility, that there are in them numerous happy strokes of humour and satire, and many felicitous phrases and descriptions, is true, but the art is on the whole heavy, awkward and forced, and the style rudely archaic and untasteful. The Latin is frequently as rough and uncouth as that of Lucilius. No doubt Varro contemned the Hellenizing innovations by which the hard and rude Latin of his youth was transformed into the polished literary language of the late republican and the Augustan age. The titles of the *Menippean Satires* are very diverse. Sometimes personal names are chosen, and they range from the gods and demigods to the slaves, from Hercules to Marcipor. Frequently a popular proverb or catchword in Greek or Latin supplies the designation: thus we have as titles "I've got You" (Ἔχω σε); "You don't Know what Evening is to Bring" (*Nescis quid vesper serus vehat*); "Know Thyself" (Γνῶθι σεαυτόν). Occasionally the heading indicates that the writer is flying at some social folly, as in "Old Men are Children for the Second Time" (Δὶς παῖδες οἱ γέροντες) and in the "Bachelor" (*Caelebs*). In many satires the philosophers were pounded, as in the "Burial of Menippus" and "Concerning the Sects" (Περὶ αἱρεσέων). Each composition seems to have been a genuine medley or *lanx satura*: any topic might be introduced which struck the author's fancy at the moment. There are many allusions to persons and events of the day, but political bitterness seems to have been commonly avoided. The whole tone of the writer is that of a *laudator temporis acti*, who can but scoff at all that has come into fashion in his own day. From the numerous citations in later authors it is clear that the *Menippean Satires* were the most popular of Varro's writings. Not very unlike the *Menippean Satires* were the *Libri Logistorici*, or satirical and practical expositions, possibly in dialogue form, of some theme most commonly taken from philosophy on its ethical side. A few fragments in this style have come down to us and a number of titles. These are twofold: that is to say, a personal name is followed by words indicating the subject-matter, as *Marius de Fortuna*, from which the contents may easily be guessed, and *Sisenna de Historia*, most likely a dialogue in which the old annalist of the name was the chief speaker, and discoursed of the principles on which history should be written. Among the lighter and more popular works may be mentioned twenty-two books of *Orations* (probably never spoken), some funeral eulogies (*Laudationes*), some "exhortations" (*Suasiones*), conceivably of a political character, and an account of the author's own life.

The second section of Varro's works, those on history and antiquities, form to the present day the basis on which a large part of our knowledge of the earlier Roman history, and in particular of Roman constitutional history, ultimately rests. These writings were used as a quarry by the compilers and dilettanti of later times, such as Pliny, Plutarch, Gellius, Festus, Macrobius, and by Christian champions like Tertullian, Arnobius and Augustine, who did not disdain to seek in heathen literature the means of defending their faith. These men have saved for us a few remains from the great wreck made by time. Judging from what has been casually preserved, if any considerable portion of Varro's labours as antiquarian and historian were to be now discovered, scholars might find themselves compelled to reconstruct the earlier history of the Roman republic from its very foundations. Varro's greatest predecessor in this field of inquiry, the man who turned over the virgin soil, was Cato the Censor. His example, however, seems to have remained unfruitful till the time of Varro's master, Lucius Aelius Stilo Praeconinus. From his age to the decay of Roman civilization there were never altogether wanting men devoted to the study of their nation's past; but none ever pursued the task with the advantages of Varro's comprehensive learning, his indefatigable industry and his reverent yet discriminating regard for the men and the institutions of the earlier ages. The greatest work of this class was that on *Antiquities*, divided into forty-one books. Of these the first twenty-five were entitled the *Antiquities of Human Things* (*Antiquitates Rerum Humanarum*), while the remaining sixteen were designated the *Antiquities of Things Divine* (*Antiquitates Rerum Divinarum*). The book was the fruit of Varro's later years, in which he gathered together the material laboriously amassed through the period of an ordinary lifetime. The second division of the work was dedicated to Caesar as supreme pontiff. The design was as far-reaching as that of the *Natural History* of Pliny. The general heads of the exposition in the secular portion of the book were four—(1) "who the men are who act (*qui agant*), (2) the places in which they act (*ubi*), (3) the times at which they act (*quando*), (4) the results of their action (*quid agant*)." In the portion relating to divine affairs there were divisions parallel to these four, with a fifth, which dealt with the gods in whose honour action in divine affairs is taken. Our knowledge of this great book is to a large extent derived from the works of the early Christian writers, and especially from Augustine's *De Civitate Dei*. These writers naturally quote in the main from the religious section. It is a great misfortune that no similar series of citations from the secular part of the *Antiquitates* has come down to us. Most of the other historical and antiquarian writings of Varro were special elaborations of topics which he could not treat with sufficient fulness and minuteness in the larger book. The treatise on the *Genealogy of the Roman People* dealt mainly with the relation of Roman chronology to the chronology of Greece and the East. Dates were assigned even to mythological occurrences, because Varro believed in the theory of Euhemerus, that all the beings worshipped as gods had once lived as men. To Varro's researches are mainly due the traditional dates assigned to the era of the kings and to that of the early republic. Minor writings of the same class were the *De Vita Populi Romani*, apparently a kind of history of Roman civilization; the *De Familiis Trojanis*, an account of the families who "came over" with Aeneas; the *Aetia* (Αἴτια), an explanation of the origin of Roman customs, on which Plutarch drew largely in his *Quaestiones Romanae*; a *Tribuum Liber*, used by Festus; and the constitutional handbook written for the instruction of Pompey when he became consul. Nor must the labour expended by Varro in the study of literary history be forgotten. His activity in this direction, as in others, took a wide range. One of his greatest achievements was to fix the canon of the genuine plays of Plautus. The "Varronian plays" were the twenty which have come down to us, along with one which has been lost.

The third class of treatises, which we have called technical, was also numerous and very varied. Philosophy, grammar, the history and theory of language, rhetoric, law, arithmetic, astronomy, geometry, mensuration, agriculture, naval tactics, were all represented. The only works of this kind which have come down to our days are the *De Lingua Latina* (in part) and the *De Re Rustica*. The former originally comprised twenty-five books, three of which (the three succeeding the first) are dedicated to a P. Septimius who had served with the author in Spain, and the last twenty-one to Cicero. The whole work was divided into three main sections, the first dealing with the origin of Latin words, the second with their inflexions and other modifications, the third with syntax. The books still preserved (somewhat imperfectly) are those from the fifth to the tenth inclusive. The Latin style is harsh, rugged and far from lucid. As Mommsen remarks, the clauses of the sentences are often arranged on the thread of the relative pronoun like thrushes on a string. The arrangement of the subject-matter, while pretending to much precision, is often far from logical. The fifth, sixth and seventh books give Varro's views on the etymology of Latin words. The principles he applies are those which he had learned from the philosophers of the Stoic school—Chrysippus, Antipater and others. The study of language as it existed in Varro's day was thoroughly dominated by Stoic influences. Varro's etymologies could be only a priori guesses, but he was well aware of their character, and very clearly states at the outset of the fifth book the hindrances that barred the way to sound knowledge. He was thoroughly alive to the importance of not arguing merely from the forms and meanings of words as they existed in his day, and was fully conscious that language and its mechanism should be studied historically. The books from the eighth to the tenth inclusive are devoted to the inflections of words and their other modifications. These Varro classes all under the head of "declinatio," which implies a swerving aside from a type. Thus *Herculi* from *Hercules* and *manubria* from *manus* are equally regarded as examples of *declinatio*. Varro adopts a compromise between the two opposing schools of grammarians, those who held that nature intended the *declinationes* of all words of the same class to proceed uniformly (which uniformity was called *analogia*) and those who deemed that nature aimed at irregularity (*anomalia*). The matter is treated with considerable confusion of thought. But the *facts* incidentally cited concerning old Latin, and the statements of what had been written and thought about language by Varro's predecessors, are of extreme value to the student of Latin. The other extant prose work, the *De Re Rustica*, is in three books, each of which is in the form of a dialogue, the circumstances and in the main the interlocutors being different for each. The dramatic introductions and a few of the interludes are bright and interesting, and the Latin style, though still awkward and unpolished, is far superior to that of the *De Lingua Latina*.

Authorities.—The fragments of the different treatises have been partially collected in many separate publications of recent date. The best editions of the *De Lingua Latina* are those by C. O. Müller and by L. Spengel (re-edited by his son in 1885). The most recent and best recension of the *De Re Rustica* is that of Keil (Leipzig, 1884). Of modern scholars Ritschl has deserved best of Varro. Several papers in his *Opuscula* treat of the nature of Varro's works which have not come down to us. The work of G. Boissier, *Étude sur la vie et les ouvrages de M. T. Varron* (1861), though superficial, is still useful; but a comprehensive work on Varro, on the present level of scholarship, is greatly needed. (J. S. R.)

VARRO, PUBLIUS TERENTIUS, surnamed Atacinus (*c.* 82–36 B.C.), Latin poet, was born near the river Atax in Gallia Narbonensis. He was perhaps the first Roman born beyond the Alps who attained eminence in literature. He seems to have taken at first Ennius and Lucilius as his models, and wrote an epic, entitled *Bellum Sequanicum*, eulogizing the exploits of Caesar in Gaul and Britain, and also *Satires*, of which Horace (*Satires*, i. 10) speaks slightingly. Accordingly to Jerome, Varro did not begin to study Greek literature until his thirty-fifth year. The last ten years of his life were given up to the imitation of Greek poets of the Alexandrian school. Quintilian (*Instit.* x. 1, 87), who describes him as a "translator," speaks of him in qualified terms of praise. Although not vigorous enough to excel in the historical epic or in the serious work of the Roman *satura*, Varro yet possessed in considerable measure the lighter gifts which we admire in Catullus.

His chief poem of the later period was the *Argonautae*, closely modelled on the epic of Apollonius Rhodius. The age was prolific of epics, both historical and mythological, and that of Varro seems to have held a high rank among them. It is highly spoken of by Ovid (*Am.* i. 15, 21, *A.A.* iii. 335, *Tristia*, ii. 439) and Statius (*Silvae*, ii. 7, 77), and Propertius (ii. 34, 85) awards equal praise to his erotic elegies. Varro was also the author of a *Cosmographia*, or *Chorographia*, a geographical poem imitated from the Greek of Eratosthenes or of Alexander of Ephesus, surnamed Lychnus; and of an *Ephemeris*, a hexameter poem on weather-signs after Aratus, from which Virgil has borrowed. Fragments in A. Riese's edition of the fragments of the *Menippean Satires* of Varro of Reate; see also monographs by F. Wüllner (1829) and R. Unger (1861).

VARTHEMA (Barthema, Vertomannus, &c.), **LUDOVICO DI,** of Bologna (fl. 1502–1510), Italian traveller and writer. He was perhaps a soldier before beginning his distant journeys, which he undertook apparently from a passion for adventure, novelty and the fame which (then especially) attended successful exploration. He left Europe near the end of 1502; early in 1503 he reached Alexandria and ascended the Nile to Cairo. From Egypt he sailed to Beirut and thence travelled to Tripoli, Aleppo and Damascus, where he managed to get himself enrolled, under the name of Yunas (Jonah), in the Mameluke garrison—doubtless after adopting Islam. From Damascus he made the pilgrimage to Mecca and Medina as one of the Mameluke escort of the Hajj caravan (April–June 1503); he describes the sacred cities of Islam and the chief pilgrim sites and ceremonies with remarkable accuracy, almost all his details being confirmed by later writers. With the view of reaching India, he embarked at Jidda, the port of Mecca, and sailed down the Red Sea and through the Straits of Bab-el-Mandeb to Aden, where he was arrested and imprisoned as a Christian spy. He gained his liberty—after imprisonment both at Aden and Radaa—through the partiality of one of the sultanas of Yemen, made an extensive tour in south-west Arabia (visiting Sana, &c.), and took ship at Aden for the Persian Gulf and India. On the way he touched at Zaila and Berbera in Somaliland; he then (early in 1504?) ran across to the Indian port of Diu in Gujarat, afterwards famous as a Portuguese fortress. From Diu he sailed up the Gulf of Cambay to Gogo, and thence turning back towards the Persian Gulf made Julfar (just within the entrance of the gulf), Muscat and Ormuz. From Ormuz he seems to have journeyed across Persia to Herat, returning thence south-west to Shiraz, where he entered into partnership with a Persian merchant, who accompanied him during nearly all his travels in South Asia. After an unsuccessful attempt to reach Samarkand, the two returned to Shiraz, came down to Ormuz, and took ship for India. From the mouth of the Indus Varthema coasted down the whole west coast of India, touching at Cambay and Chaul; at Goa, whence he made an excursion inland to Bijapur; at Cannanore, from which he again struck into the interior to visit Vijayanagar on the Tungabudra; and at Calicut (1505?), where he stops to describe the society, manners and customs of Malabar, as well as the topography and trade of the city, the court and government of its sovereign (the Zamorin), its justice, religion, navigation and military organization. Nowhere do Varthema's accuracy and observing power show themselves more strikingly. Passing on by the "backwater of Cochin," and calling at Kulam (Quilon), he rounded Cape Comorin, and passed over to Ceylon (1506?). Though his stay here was brief (at Colombo?), he learnt a good deal about the island, from which he sailed to Pulicat, slightly north of Madras, then subject to Vijayanagar. Thence he crossed over to Tenasserim in the Malay Peninsula, to Banghella, perhaps near Chittagong, at the head of the Bay of Bengal, and to Pegu, in the company of his Persian friend and of two Chinese Christians (Nestorians?) whom he met at Banghella. After some successful trading with the king of Pegu, Varthema and his party sailed on to Malacca, crossed over to Pider (Pedir) in Sumatra, and thence proceeded to Bandan (Banda) and Monoch (one of the Moluccas), the farthest eastward points reached by the Italian traveller. From the Moluccas he returned westward, touched at Borneo, and there chartered a vessel for Java, the "largest of islands," as his Christian companions reckoned it. He notes the use of compass and chart by the native captain on the transit from Bornei to Giava, and preserves a curious, more than half-mythical, reference to supposed Far Southern lands. From Java he crossed over to Malacca, where he and his Persian ally parted from the Chinese Christians; from Malacca he returned to the Coromandel coast, and from Negapatam (?) in Coromandel he voyaged back, round Cape Comorin, to Kulam and Calicut. Varthema was now anxious to resume Christianity and return to Europe; after some time he succeeded in deserting to the Portuguese garrison at Cannanore (early in 1506?). He fought for the Portuguese in various engagements, and was knighted by the viceroy Francisco d'Almeida, the navigator Tristan da Cunha being his "sponsor." For a year and a half he acted as Portuguese factor at Cochin, and on the 6th of December 1507 (?) he finally left India for Europe by the Cape route. Sailing from Cannanore, Varthema apparently struck Africa about Malindi, and (probably) coasting by Mombasa and Kilwa arrived at Mozambique, where he notices the Portuguese fortress then building, and describes with his usual accuracy the negroes of the mainland. Beyond the Cape of Good Hope he encountered furious storms, but arrived safely in Lisbon after sighting St Helena and Ascension, and touching at the Azores. In Portugal the king received him cordially, kept him some days at court "to learn about India," and confirmed the knighthood conferred by d'Almeida. His narrative finally brings him to Rome, where he takes leave of the reader. As Richard Burton says (*Pilgrimage to . . . Meccah*, 1855, vol. ii. p. 352): "For correctness of observation and readiness of wit" Varthema "stands in the foremost rank of the old Oriental travellers." In Arabia and in the Indian archipelago east of Java he is (for Europe and Christendom) a real discoverer. Even where passing over ground traversed by earlier European explorers, his keen intelligence frequently adds valuable original notes on peoples, manners, customs, laws, religions, products, trade, methods of war, &c.

Varthema's work (*Itinerario de Ludouico de Varthema Bolognese . . .*) was first published in Italian at Rome in 1510 (*ad instãtia de Lodouico de Henricis da Corneto Vicẽtino*). Other Italian editions appeared at Rome, 1517, at Venice, 1518, 1535, 1563, 1589, &c., at Milan, 1519, 1523, 1525, &c. Latin translations appeared at Milan, 1511 (by Archangelus Madrignanus); and at Nuremberg, 1610 (Frankfort, 1611); as well as in the *Novus Orbis* of Simon Grynaeus (Basel, 1532). German versions came out at Augsburg, 1515 (Strassburg, 1516); at Strassburg, by Michael Herr, in his *New Welt*, from Grynaeus, 1534; at Leipzig, by Hieronymus Megiserus, 1610 (and 1615), &c. A Spanish translation was issued at Seville, 1520 (from the Latin), and a French at Lyons, 1556. Dutch versions were printed at Antwerp, 1563 (from Grynaeus), at Utrecht, 1615 (from the Leipzig German of 1610), and again at Utrecht, 1655. The first English translation was of 1576–1577 (in Richard Eden's *History of Travayle*); an extract from Varthema was inserted in Samuel Purchas's *Pilgrimage* (London, 1625–1626); and in 1863 appeared the Hakluyt Society edition by J. W. Jones and G. P. Badger (*Travels of Ludovico di Varthema*, London). (C. R. B.)

VARUNA, in early Hindu mythology, the greatest, with Indra, of the gods of the Rig Veda. He is invoked with his double Mitra in some dozen hymns. As contrasted with Indra the war god, Varuna is the lord of the natural laws, the upholder of the physical and moral order of the universe. His power is limitless, his anger at wrong-doing unassuageable, and he is omniscient. He makes the sunshine; the wind is his breath; river valleys are hollowed out at his command. Unlike Indra, Varuna has no myths related of him. In the later Vedic period he is specially connected with the nocturnal heavens. Ultimately in post-Vedic mythology he becomes the Hindu Neptune. The earlier conception of Varuna is singularly similar to that of Ahuramazda of the Avesta. The name Varuna may be Indo-European, identifiable, some believe, with the Greek *οὐρανός* (Uranus), and ultimately referable to a root *var*, "to cover," Varuna thus meaning "the Encompasser." Among Varuna's aliases are Jalapati, "Lord of Water," and Amburaja, "King of Water."

See A. A. Macdonell, *Vedic Mythology* (Strassburg, 1897).

VASA, or NIKOLAISTAD, in the grand duchy of Finland, capital of the province of Vasa, on the east coast of the Gulf of Bothnia, 327 m. by rail north-west of Helsingfors. Pop. (1904) 18,028. It has two classical lyceums for boys and three for girls, a school of navigation, and a large number of primary schools. There is a shipyard and a considerable export trade. Vasa was founded on the coast of the Gulf of Bothnia in 1606, but after the great fire of 1852, as the sea had already receded for a considerable distance, the town was rebuilt nearer to the shore and received the official name of Nikolaistad. The population of the province (1904) was 295,187.

VASARI, GIORGIO (1511–1571), Italian painter and architect, whose main distinction, however, rests on his valuable history of Italian art, was born at Arezzo on the 30th of July 1511. At a very early age he became a pupil of Guglielmo da Marsiglia, a very skilful painter of stained glass, to whom he was recommended by his own kinsman, the painter Luca Signorelli. At the age of sixteen he went to Florence, where he studied under Michelangelo and Andrea del Sarto, aided by the patronage of the Medici princes. In 1529 he visited Rome and studied the works of Raphael and others of his school. The paintings of Vasari were much admired by the rapidly degenerating taste of the 16th century; but they possess the smallest amount of merit, being in the main feeble parodies of the powerful works of Michelangelo. Vasari was largely employed in Florence, Rome, Naples, Arezzo and other places. Many of his pictures still exist, the most important being the wall and ceiling paintings in the great hall of the Palazzo Vecchio in Florence, and his frescoes on the cupola of the cathedral, which, however, were not completed at the time of his death. As an architect he was perhaps more successful: the loggia of the Uffizi by the Arno, and the long passage connecting it with the Pitti Palace, are his chief works. Unhappily he did much to injure the fine medieval churches of S. Maria Novella and Santa Croce, from both of which he removed the original rood-screen and loft, and remodelled the retro-choir in the degraded taste of his time. Vasari enjoyed a very high repute during his lifetime and amassed a considerable fortune. He built himself in 1547 a fine house in Arezzo, and spent much labour in decorating its walls and vaults with paintings. He was elected one of the municipal council or priori of his native town, and finally rose to the supreme office of gonfaloniere. He died at Florence on the 27th of June 1571.

Personally Vasari was a man of upright character, free from vanity, and always ready to appreciate the works of others: in spite of the narrow and meretricious taste of his time, he expresses a warm admiration of the works of such men as Cimabue and Giotto, which is very remarkable. As an art historian of his country he must always occupy the highest rank. His great work was first published in 1550, and afterwards partly rewritten and enlarged in 1568, bearing the title *Delle Vite de' più eccellenti pittori, scultori, ed architettori.* It was dedicated to Cosimo de' Medici, and was printed at Florence by the Giunti; it is a small quarto illustrated with many good woodcut portraits. This *editio princeps* of the complete work is usually bound in three volumes, and also contains a very valuable treatise on the technical methods employed in all branches of the arts, entitled *Le Tre Arti del disegno, cioè architettura, pittura, e scoltura.* His biographies are written in a very pleasant style, interspersed with amusing stories. With a few exceptions Vasari's judgment is acute and unbiased. And though modern criticism—with all the new materials opened up by research—has done valuable work in upsetting a good many of his traditional accounts and attributions, the result is a tendency very often to underestimate Vasari's accuracy and to multiply hypotheses of a rather speculative character. The work in any case remains a classic, however it may be supplemented by the more critical research of modern days.

Vasari gives a sketch of his own biography at the end of his *Vite*, and adds further details about himself and his family in his lives of Lazzaro Vasari and Francesco Salviati. The best edition of Vasari's works is that published at Florence by Milanesi (1878–1882), which embodies the valuable notes in the earlier edition by Le Monnier (1846); another, by Venturi, was begun in 1896. The *Lives* has been translated into French, German and English (by Mrs Foster, London, 1850).

VASCULAR SYSTEM. I. Anatomy.—The circulatory or blood vascular apparatus consists of the central pump or heart, the arteries leading from it to the tissues, the capillaries, through the walls of which the blood can give and receive substances to and from the tissues of the whole body, and the veins, which return the blood to the heart. As an accessory to the venous system, the lymphatics, which open finally into the great veins, help in returning some of the constituents of the blood. Separate articles are devoted to the *heart, arteries, veins* and *lymphatic* system, and it only remains here to deal with the capillaries.

The *blood capillaries* form a close network of thin-walled tubules from $\frac{1}{2000}$ to $\frac{1}{3000}$ of an inch in diameter, permeating, with a few exceptions, the whole of the body, and varying somewhat in the closeness of its meshwork in different parts. In the smallest capillaries, in which the arteries end and from which the veins begin, the walls are formed only of somewhat oval endothelial cells, each containing an oval nucleus and joined to its adjacent cells by a serrated edge, in the interstices of which is a small amount of intercellular cement, easily demonstrated by staining the preparation with nitrate of silver. Here and there the cement substance is more plentiful, and these spots when small are known as *stigmata*, when large as *stomata*. As the capillaries approach the arteries on the one hand and the veins on the other they blend and become larger, and a delicate connective tissue sheath outside the endothelium appears, so that the transition from the capillaries into the arterioles and venules is almost imperceptible; indeed, the difference between a large artery or vein and a capillary, apart from size, is practically the amplification and differentiation of its connective tissue sheath.

Embryology.—The first appearance of a vascular system is outside the body of the embryo in the wall of the yolk sac, that is to say, in the mesoderm or the middle one of the three embryonic layers. The process is a very early one and in the chick is seen to begin at the end of the first day of incubation. The first occurrence is a network made up of solid cords of cells forming in certain places solid cell masses called the *blood islands of Pander*. The central cells of these islands divide by karyokinesis and gradually float away into the vessels which are now being formed by fluid from the exterior, finding its way into the centre of the cell cords and pressing the peripheral cells flat to form the endothelial lining. These free cells from the blood islands are known as *erythroblasts* and are the primitive corpuscles of the foetal blood. They have a large reticular nucleus and at first are colourless though haemoglobin gradually develops within them and the blood becomes red (see Blood). The erythroblasts continue to multiply by karyokinesis in early foetal life, especially in the liver, spleen, bone marrow and lymphatic glands, though later on their formation only occurs in the red bone marrow. In most of the erythroblasts the nucleus soon becomes contracted, and the cell is then known as a *normoblast*, while ultimately the general view is that the nucleus disappears by extrusion from the cell and the non-nucleated red blood plates or *erythrocytes* remain. The leucocytes or white blood corpuscles appear later than the red, and are probably formed from lymphoid tissue in various parts of the body. The blood vessels thus formed in the so-called vascular area gradually travel along the vitelline stalk into the body of the embryo, and two vessels larger than the rest are formed one on each side of the stalk. These are the vitelline veins, which, as they pass towards the caudal end of the embryo, become the two primitive aortae, and these fuse later on to form the heart. After the inversion of the pericardial region and formation of the head fold (see Coelom and Serous Membranes) the front of the developing heart becomes the back, and the vitelline veins now enter it from behind. It must be understood that most of our knowledge of the early history of the blood vessels is derived from the study of lower mammals and birds, and that this is being gradually checked by observations on human embryos and on those of other primates. It seems probable that in these mammals, owing to the small size of the yolk sac, the vessels of the embryo establish an early communication with those of the chorion before the vitelline veins are formed (see Quain's *Anatomy*, vol. i., London, 1908). The later stages of the embryology of the vascular system are sketched in the articles on Heart, Arteries, Veins and Lymphatic System (*q.v.*). (F. G. P.)

II. History of Discovery

Galen. Galen, following Erasistratus (*ob.* 280 B.C.) and Aristotle, clearly distinguished arteries from veins, and was the first to overthrow the old theory of Erasistratus that the arteries contained air. According to him, the vein arose from the liver in two great trunks, the *vena porta* and *vena cava*. The first was formed by the union of all the abdominal veins, which absorbed the chyle prepared in the stomach and intestines, and carried it to the liver, where it was converted into blood. The vena cava arose in the liver, divided into two branches, one ascending through the diaphragm to the heart, furnishing the proper veins of this organ; there it received the *vena azygos*, and entered the right ventricle, along with a large trunk from the lungs, evidently the pulmonary artery. The vena azygos was the *superior vena cava*, the great vein which carries the venous blood from the head and upper extremities into the right auricle. The descending branch of the great trunk supposed to originate in the liver was the *inferior vena cava*, below the junction of the hepatic vein. The arteries arose from the left side of the heart by two trunks, one having thin walls (the pulmonary veins), the other having thick walls (the aorta). The first was supposed to carry blood to the lungs, and the second to carry blood to the body. The heart consisted of two ventricles, communicating by pores in the septum; the lungs were parenchymatous organs communicating with the heart by the pulmonary veins. The blood-making organ, the liver, separates from the blood subtle vapours, the *natural spirits*, which, carried to the heart, mix with the air introduced by respiration, and thus form the *vital spirits*; these, in turn carried to the brain, are elaborated into *animal spirits*, which are distributed to all parts of the body by the nerves.[1] Such were the views of Galen, taught until early in the 16th century.

Vesalius. Jacobus Berengarius of Carpi (*ob.* 1530) investigated the structure of the valves of the heart. Andreas Vesale or Vesalius (1514–1564) contributed largely to anatomical knowledge, especially to the anatomy of the circulatory organs. He determined the position of the heart in the chest;

[1] See Burggraeve's *Histoire de l'anatomie* (Paris, 1880).

he studied its structure, pointing out the fibrous rings at the bases of the ventricles; he showed that its wall consists of layers of fibres connected with the fibrous rings; and he described these layers as being of three kinds—straight or vertical, oblique, and circular or transverse. From the disposition of the fibres he reasoned as to the mechanism of the contraction and relaxation of the heart. He supposed that the relaxation, or diastole, was accounted for principally by the longitudinal fibres contracting so as to draw the apex towards the base, and thus cause the sides to bulge out; whilst the contraction, or systole, was due to contraction of the transverse or oblique fibres. He showed that the pores of Galen, in the septum between the ventricles, did not exist, so that there could be no communication between the right and left sides of the heart, except by the pulmonary circulation. He also investigated minutely the internal structure of the heart, describing the valves, the *columnae carneae* and the *musculi papillares*. He described the mechanism of the valves with much accuracy. He had, however, no conception either of a systemic or of a pulmonary circulation. To him the heart was a reservoir from which the blood ebbed and flowed, and there were two kinds of blood, arterial and venous, having different circulations and serving different purposes in the body. Vesalius was not only a great anatomist: he was a great teacher; and his pupils carried on the work in the spirit of their master. Prominent among them was Gabriel Fallopius (1523–1562), who studied the anastomoses of the blood vessels, without the art of injection, which was invented by Frederick Ruysch (1638–1731) more than a century later. Another pupil was Columbus (Matthieu Reald Columbo, *ob.* 1560), first a prosector in the anatomical rooms of Vesalius and afterwards his successor in the chair of anatomy in Padua; his name has been mentioned as that of one who anticipated Harvey in the discovery of the circulation of the blood. A study of his writings clearly shows that he had no true knowledge of the circulation, but only a glimpse of how the blood passed from the right to the left side of the heart. In his work there is evidently a sketch of the pulmonary circulation, although it is clear that he did not understand the mechanism of the valves, as Vesalius did. As regards the systemic circulation, there is the notion simply of an oscillation of the blood from the heart to the body and from the body to the heart. Further, he upholds the view of Galen, that all the veins originate in the liver; and he even denies the muscular structure of the heart.[1]

Columbus.

Servetus.

In 1553 Michael Servetus (1511–1553), a pupil or junior fellow-student of Vesalius, in his *Christianismi Restitutio*, described accurately the pulmonary circulation.[2] Servetus perceived the course of the circulation from the right to the left side of the heart through the lungs, and he also recognized that the change from venous into arterial blood took place in the lungs and not in the left ventricle. Not so much the recognition of the pulmonary circulation, as that had been made previously by Columbus, but the discovery of the respiratory changes in the lungs constitutes Servetus's claim to be a pioneer in physiological science.

Cesalpino.

Andrea Cesalpino (1519–1603), a great naturalist of this period, also made important contributions towards the discovery of the circulation, and in Italy he is regarded as the real discoverer.[3] Cesalpino knew the pulmonary circulation. Further, he was the first to use the term "circulation," and he went far to demonstrate the systemic circulation. He experimentally proved that, when a vein is tied, it fills below and not above the ligature. The following passage from his *Quaestiones Medicae* (lib. v. cap. 4, fol. 125), quoted by Gamgee, shows his views:—

"The lungs, therefore, drawing the warm blood from the right ventricle of the heart through a vein like an artery, and returning it by anastomosis to the venal artery (pulmonary vein), which tends towards the left ventricle of the heart, and air, being in the meantime transmitted through the channels of the aspera arteria (trachea and bronchial tubes), which are extended near the venal artery, yet not communicating with the aperture as Galen thought, tempers with a touch only. This circulation of the blood (*huic sanguinis circulationi*) from the right ventricle of the heart through the lungs into the left ventricle of the same exactly agrees with what appears from dissection. For there are two receptacles ending in the right ventricle and two in the left. But of the two only one intromits; the other lets out, the membranes (valves) being constituted accordingly."

Still Cesalpino clung to the old idea of there being an efflux and reflux of blood to and from the heart, and he had confused notions as to the veins conveying nutritive matter, whilst the arteries carried the vital spirits to the tissues. He does not even appear to have thought of the heart as a contractive and propulsive organ, and attributed the dilatation to "an effervescence of the spirit," whilst the contraction—or, as he termed it, the "collapse"—was due to the appropriation by the heart of nutritive matter. Whilst he imagined a communication between the termination of the arteries and the commencement of the veins, he does not appear to have thought of a direct flow of blood from the one to the other. Thus he cannot be regarded as the true discoverer of the circulation of the blood. More recently Ercolani has put forward claims on behalf of Carlo Ruini as being the true discoverer. Ruini published the first edition of his anatomical writings in 1598, the year William Harvey entered at Padua as a medical student. This claim has been carefully investigated by Gamgee, who has come to the conclusion that it cannot be maintained.[4]

Discovery of circulation of blood.

The anatomy of the heart was examined, described and figured by Bartolomeo Eustacheo (*c.* 1500–1574) and by Julius Caesar Aranzi or Arantius (*c.* 1530–1589), whose name is associated with the fibro-cartilaginous thickenings on the free edge of the semilunar valves (*corpora Arantii*). Hieronymus Fabricius of Acquapendente (1537–1619), the immediate predecessor and teacher of Harvey, made the important step of describing the valves in the veins; but he thought they had a subsidiary office in connexion with the collateral circulation, supposing that they diverted the blood into branches near the valves; thus he missed seeing the importance of the anatomical and experimental facts gathered by himself. At the time when Harvey arose the general notions as to the circulation may be briefly summed up as follows: the blood ebbed and flowed to and from the heart in the arteries and veins; from the right side at least a portion of it passed to the left side through the vessels in the lungs, where it was mixed with air; and, lastly, there were two kinds of blood—the venous, formed originally in the liver, and thence passing to the heart, from which it went out to the periphery by the veins and returned by those to the heart; and the arterial, containing "spirits" produced by the mixing of the blood and the air in the lungs—sent out from the heart to the body and returning to the heart by the same vessels. The pulmonary circulation was understood so far, but its relation to the systemic circulation was unknown. The action of the heart, also, as a propulsive organ was not recognized. It was not until 1628 that Harvey announced his views to the world by publishing his treatise *De Motu Cordis et Sanguinis*. His conclusions are given in the following celebrated passage:—

Harvey.

"And now I may be allowed to give in brief my view of the circulation of the blood, and to propose it for general adoption. Since all things, both argument and ocular demonstration, show that the blood passes through the lungs and heart by the auricles and

[1] An interesting account of the views of the precursors of Harvey will be found in Willis's edition of the *Works* of Harvey, published by the Sydenham Society. Compare also P. Flourens, *Histoire de la decouverte de la circulation du sang* (Paris, 1854), and Professor R. Owen, *Experimental Physiology, its Benefits to Mankind, with an Address on Unveiling the Statue of W. Harvey, at Folkestone, 6th August 1881.*

[3] A learned and critical series of articles by Sampson Gamgee in the *Lancet*, in 1876, gives an excellent account of the controversy as to whether Cesalpino or Harvey was the true discoverer of the circulation; see also the Harveian oration for 1882 by George Johnston (*Lancet*, July 1882), and Professor G. M. Humphry, *Journ. Anat. and Phys.*, October 1882.

[4] Gamgee, "Third Historical Fragment," in *Lancet*, 1876.

ventricles, and is sent for distribution to all parts of the body, where it makes its way into the veins and pores of the flesh, and then flows by the veins from the circumference on every side to the centre, from lesser to the greater veins, and is by them finally discharged into the vena cava and right auricle of the heart, and this in such a quantity, or in such a flux and reflux, thither by the arteries, hither by the veins, as cannot possibly be supplied by the ingestor, and is much greater than can be required for mere purposes of nutrition, it is absolutely necessary to conclude that the blood in the animal body is impelled in a *circle*, and is in a state of ceaseless motion, that this is the act or function which the heart performs by means of its pulse, and that it is the sole and only end of the motion and contraction of the heart" (bk. x. ch. xiv. p. 68).

Opposed to Caspar Hofmann of Nuremberg (1571–1623), Veslingius (Vesling) of Padua (1598–1649), and J. Riolanus the younger, this new theory was supported by Roger Drake, a young Englishman, who chose it for the subject of a graduation thesis at Leiden in 1637, by Werner Rolfinck of Jena (1599–1673), and especially by Descartes, and quickly gained the ascendant; and its author had the satisfaction of seeing it confirmed by the discovery of the capillary circulation, and universally adopted. The circulation in the capillaries between the arteries and the veins was discovered by Marcellus Malpighi (1628–1694) of Bologna in 1661. He saw it first in the lungs and the mesentery of a frog, and the discovery was announced in the second of two letters, *Epistola de Pulmonibus*, addressed to Borelli, and dated 1661.[1] Malpighi actually showed the capillary circulation to the astonished eyes of Harvey. Anthony van Leeuwenhoek (1632–1723) in 1673 repeated Malpighi's observations, and studied the capillary circulation in a bat's wing, the tail of a tadpole and the tail of a fish. William Molyneux studied the circulation in the lungs of a water newt in 1683.[2]

Capillary circulation.

The idea that the same blood was propelled through the body in a circuit suggested that life might be sustained by renewing the blood in the event of some of it being lost. About 1660 Lower, a London physician (died 1691), succeeded in transferring the blood of one animal directly from its blood vessels into those of another animal. This was first done by passing a "quill" or a "small crooked pipe of silver or brass" from the carotid artery of one dog to the jugular vein of another.[3] This experiment was repeated and modified by Sir Edmund King (1629–1709), Thomas Coxe (1615–1685), Gayant and Denys with such success as to warrant the operation being performed on man, and accordingly it was carried out by Lower and King on the 23rd of November 1667, when blood from the arteries of a sheep was directly introduced into the veins of a man.[4] It would appear that the operation had previously been performed with success in Paris.

Transfer of blood.

The doctrine of the circulation being accepted, physiologists next directed their attention to the force of the heart, the pressure of the blood in the vessels, its velocity, and the phenomena of the pulse wave. Giovanni Alphonso Borelli (1608–1679) investigated the circulation during the lifetime of Harvey. He early conceived the design of applying mathematical principles to the explanation of animal functions; and, although he fell into many errors, he must be regarded as the founder of animal mechanics. In his *De Motu Animalium* (1680–85) he stated his theory of the circulation in eighty propositions, and in prop. lxxiii., founding on a supposed relation between the bulk and the strength of muscular fibre as found in the ventricles, erroneously concluded that the force of the heart was equal to the pressure of a weight of 180,000 ℔. He also recognized and figured the spiral arrangement of fibres in the ventricles. The question was further investigated by James Keill, a Scottish physician (1673–1719), who in his *Account of Animal Secretion, the Quantity of Blood in the Human Body, and Muscular Motion* (1708) attempted to estimate the velocity of blood in the aorta, and gave it at 52 ft. per minute. Then, allowing for the resistance of the vessels, he showed that the velocity diminishes towards the smaller vessels, and arrived at the amazing conclusion that in the smallest vessels it travels at the rate of $\frac{1}{4}$ in. in 278 days,—a good example of the extravagant errors made by the mathematical physiologists of the period. Keill further described the hydraulic phenomena of the circulation in papers communicated to the Royal Society and collected in his *Essays on Several Parts of the Animal Oeconomy* (1717). In these essays, by estimating the quantity of blood thrown out of the heart by each contraction, and the diameter of the aortic orifice, he calculated the velocity of the blood. He stated (pp. 84, 87) that the blood sent into the aorta with each contraction would form a cylinder 8 in. (2 oz.) in length and be driven along with a velocity of 156 ft. per minute. Estimating then the resistances to be overcome in the vessels, he found the force of the heart to be "little above 16 oz.," —a remarkable difference from the computation of Borelli. Keill's method was ingenious, and is of historical interest as being the first attempt to obtain quantitative results; but it failed to obtain true results, because the data on which he based his calculations were inaccurate. These calculations attracted the attention not only of the anatomico-physiologists, such as Haller, but also of some of the physicists of the time, notably of Jurin and D. Bernoulli. Jurin (died 1750) gave the force of the left ventricle at 9 ℔ 1 oz., and that of the right ventricle at 6 ℔ 3 oz. He also stated with remarkable clearness, considering that he reasoned on the subject as a physicist, without depending on experimental data gathered by himself, the influence on the pulse induced by variations in the power of the heart or in the resistance to be overcome.[5] The experimental investigation of the problem was supplied by Stephen Hales (1677–1761), rector of Teddington in Middlesex, who in 1708 devised the method of estimating the force of the heart by inserting a tube into a large artery and observing the height to which the blood was impelled into it. Hales is the true founder of the modern experimental method in physiology. He observed in a horse that the blood rose in the vertical tube, which he had connected with the crural artery, to the height of 8 ft. 3 in. perpendicular above the level of the left ventricle of the heart. But it did not attain its full height at once: it rushed up about half-way in an instant, and afterwards gradually at each pulse 12, 8, 6, 4, 2, and sometimes 1 in. When it was at its full height, it would rise and fall at and after each pulse 2, 3 or 4 in.; and sometimes it would fall 12 or 14 in., and have there for a time the same vibrations up and down at and after each pulse as it had when it was at its full height, to which it would rise again after forty or fifty pulses.[6] He then estimated the capacity of the left ventricle by a method of employing waxen casts, and, after many such experiments and measurements in the horse, ox, sheep, fallow deer and dog, he calculated that the force of the left ventricle in man is about equal to that of a column of blood $7\frac{1}{2}$ ft. high, weighing $51\frac{1}{2}$ ℔, or, in other words, that the pressure the left ventricle has to overcome is equal to the pressure of that weight. When we contrast the enormous estimate of Borelli (180,000 ℔) with the under-estimate of Keill (16 oz.), and when we know that the estimate of Stephen Hales (1677–1761), as corroborated by recent investigations by means of elaborate scientific appliances, is very near the truth, we recognize the far higher service rendered to science by careful and judicious experiment than by speculations, however ingenious. With the exception of some calculations by Dan Bernoulli (1700–1782) in 1748, there was no great contribution to haemadynamics till 1808, when two remarkable papers appeared from Thomas Young (1773–1829). In the first, entitled "Hydraulic Investigations," which appeared in the *Phil. Trans.*, he investigated the friction and discharge of fluids running in pipes and the velocity of rivers, the

resistance occasioned by flexures in pipes and rivers, the propagation of an impulse through an elastic tube, and some of the phenomena of pulsations. This paper was preparatory to the second, "On the Functions of the Heart and Arteries,"—the Croonian lecture for 1808—in which he showed more clearly than had hitherto been done (1) that the blood pressure gradually diminishes from the heart to the periphery; (2) that the velocity of the blood becomes less as it passes from the greater to the smaller vessels; (3) that the resistance is chiefly in the smaller vessels, and that the elasticity of the coats of the great arteries comes into play in overcoming this resistance in the interval between systoles; and (4) that the contractile coats do not act as propulsive agents, but assist in regulating the distribution of blood.[1]

The next epoch of physiological investigation is characterized by the introduction of instruments for accurate measurement, and the graphic method of registering phenomena, now so largely used in science.[2] In 1825 appeared E. and Wilhelm Weber's (1804–1891) *Wellenlehre*, and in 1838 Ernest Weber's (1795–1878) *Ad Notat. Anatom. et Physiolog.* i., both of which contain an exposition of E. H. Weber's *schema* of the circulation, a scheme which presents a true and consistent theory. In 1826 Jean Louis Marie Poiseuille invented the haemadynamometer.[3] This was adapted with a marker to a recording cylinder by Ludwig in 1847, so as to form the instrument named by Alfred Volkmann (1801–1877) the kymograph. Volkmann devised the haemadromometer for measuring the velocity of the blood in 1850; for the same purpose Vierordt constructed the haematachometer in 1858; Chauveau and Pierre Lortet (1792–1868) first used their haemadromograph in 1860; and lastly, Ludwig and Dogiel obtained the best results as regards velocity by the "stream-clock" in 1867. As regards the pulse, the first sphygmograph was constructed by Karl Vierordt (1818–1884) in 1856; and Étienne Marey's form, of which there are now many modifications, appeared in 1860. In 1861 Jean Chauveau (b. 1827) and Marey obtained tracings of the variations of pressure in the heart cavities (see below), by an experiment which is of great historical importance. During the past twenty-five years vast accumulations of facts have been made through the instruments of precision above alluded to, so that the conditions of the circulation, as a problem in hydrodynamics, have been thoroughly investigated. Since 1845, when the brothers Weber discovered the inhibitory action of the vagus, and 1858, when Claude Bernard (1813–1878) formulated his researches showing the existence of a vaso-motor system of nerves, much knowledge has been acquired as to the relations of the nervous to the circulatory system. The Webers, John Reid (1816–1895), Claude Bernard and Carl Ludwig (1809–1849) may be regarded as masters in physiology equal in standing to those whose researches have been more especially alluded to in this historical sketch. The Webers took the first step towards recognizing the great principle of inhibitory action; John Reid showed how to investigate the functions of nerves by his classical research on the eighth pair of cranial nerves; Claude Bernard developed the fundamental conception of vaso-motor nerves; and Ludwig showed how this conception, whilst it certainly made the hydraulic problems of the circulation infinitely more complicated than they were even to the scientific imagination of Thomas Young, accounted for some of the phenomena and indicated at all events the solidarity of the arrangements in the living being. Further, Ludwig and his pupils used the evidence supplied by some of the phenomena of the circulation to explain even more obscure phenomena of the nervous system, and they taught pharmacologists how to study in a scientific manner the physiological action of drugs. (J. G. M.)

III. Physiology

The unicellular animal immersed in water absorbs nutritive matter and oxygen, and excretes waste materials with its whole surface. Owing to the small mass of the protozoa the metabolic products can penetrate throughout the whole. With the evolution of the multicellular organs of the metazoa and the division of physiological labour a circulatory mechanism became of immediate need. A double-layered animal like the common water polype Hydra can exist, it is true, without such a mechanism, but communities of polypes, such as the sponges, form channels for the circulation of water. With the development of the three-layered animal the coelom or body cavity arose by the splitting of the mesoderm, and it was in this body cavity that the evolution of the circulatory system took place, an evolution which finally became perfected in the higher members of the metazoa into a closed vascular system filled with red blood. The evolution of the red matter, haemoglobin, as a special carrier of oxygen was necessitated by the increasing mass and muscular activity of the higher animal, in comparison with the size of the oxygen-absorbing surface—the gill or lung. The blood vascular system of the invertebrata such as the Arthropoda and Insecta, is not generally a closed system, but consists of a pulsatile heart whence proceed arteries which open into lacunar spaces forming part of the coelom. The lacunae exist between the organs and tissues of the body, and the blood from these spaces is returned to a venous sinus whence the heart draws its supply through valved openings. The movements of the animal help to return the blood from the tissue spaces to the heart, while the heart by its rhythmic contraction drives the blood into the arteries. Somewhere in the course of this system are placed the gills and renal organs, and it appears to be a matter of indifference whether the gills be placed on the arterial or venous side of the system, both arrangements being found in different types. In some types (mussel, earthworm), the whole blood passes through the renal organs at each circulation, in others (crayfish) only parts. In the earthworm the vascular system is closed, the arteries and veins being connected by capillaries in place of lacunae. The movement of tissue juices may be maintained by physico-chemical forces alone, *e.g.* by the forces of osmosis and adsorption, as is seen in the movements of sap in the vascular bundles of plants, in the streaming of protoplasm in the plant cell and in the marvellous rhythmic to-and-fro movements of the richly granular juice contained in the veins of the spreading protoplasmic sheet of myxomycetes. Such agencies come into play in the lacunar or capillary part of the circulation of the metazoa and are assisted by the movements of the body wall and of the alimentary organs. The evolution of a special pumping organ, the heart, associated with the aeration of the body fluids in the gills, led to the perfection of the efficient system of circulation which is found in the vertebrata.

The general principles of the circulation.

The blood is to be regarded as alive in as strict a sense as any other component of the living body. It is a tissue consisting of mobile elements—the blood corpuscles—and a plasma—a colloidal albuminous fluid which is analogous to the more solid intercellular material of other tissues. The primary sources of its elements are the blood-forming organs—the bone marrow, the haemolymph and lymphatic glands and other lymphatic tissue, and the spleen. It circulates as the middleman between the tissues, conveying from the alimentary canal the products of digestion—sugar, fat, amino-acids and salts; oxygen from the lungs; carbonic acid, urea and other waste products of the tissues to the lungs and kidneys; internal secretions from one organ to another; and acts not only as a carrier, but deals with the material remitted to it on the way. One other function of the blood, a most important one, must not be omitted, that of defence against the invasion of bacteria and their toxins, and other parasites.

The blood is contained in a continuous system of vessels; *arteries* lead from the heart and divide into a multitude of *capillary* vessels, and these lead into the *veins* which finally pass back to the heart. The heart is to be regarded as a double organ, each half consisting of an *auricle* and a *ventricle*. The right half contains dark venous blood which has been returned from the body and is sent to the lungs: the left heart contains the bright oxygenated blood which has been returned from the lungs and is distributed to the body. There are thus two circulations—the one *pulmonary*, from the right side of the heart to the pulmonary artery and thence to the capillaries of the lungs and to the left heart by the pulmonary veins—the other *systemic*, from the left side of the heart, by the aorta, to the arteries and capillaries of the body tissues and organs, whence the blood returns by the veins to the right side of the heart.

The course of the circulation in mammals.

A schematic representation is given of the circulatory system in the accompanying diagram. The venous blood flows into the right auricle (RA) from the superior vena cava and the inferior vena cava. The right ventricle (RV) drives through the lungs the blood received from the right auricle. The right auriculo-ventricular valve, or tricuspid, and the pulmonary semilunar valve are represented directing the flow of blood in this direction. From the pulmonary capillaries the blood

FIG. 1.—General Course of Circulation and some of the Principal Vessels. returns by the pulmonary veins (PV) into the left auricle (LA), and so through the left auriculo-ventricular or mitral valve into the left ventricle (LV). By the left ventricle the blood is driven through the aortic semilunar valve, and is distributed to the systemic arteries, and so to the capillaries of the various organs and back to the veins. The muscular wall of the auricles and that of the right ventricle are much thinner than that of the left ventricle. This is so, because the energy required of the left ventricle must exceed that of the right ventricle, inasmuch as the resistance in the systemic system exceeds that in the pulmonary circuit.

The heart fills with venous blood during its expansion or *diastole*, and forces the blood into the arteries during its contraction or *systole*. The large arteries are of less capacity than the corresponding veins, and their walls are essentially extensile and elastic. The pulmonary arteries are especially extensile structures. The small arteries and *arterioles* are essentially muscular tubes and can vary considerably in diameter. The arterioles open into the capillaries, and these are so numerous that each organ may be regarded as a sponge full of blood. The skeletal muscles and the muscular walls of the viscera at each contraction express the blood within them, and materially influence the circulation. The whole muscular system, as well as the heart, must therefore be regarded as a pump to the vascular system. The capillary wall is composed of a single layer of flattened cells, separating the blood within from the tissues without. Through this layer, which is of extraordinary tenuity, there takes place an exchange of material between the blood and the tissues, an exchange which depends on the physico-chemical conditions which characterize the living state of the cells. The phenomena of adsorption and osmosis come into play here, but the conditions still await complete elucidation. The veins are of larger calibre than the corresponding arteries, and have tough and inextensile walls. Their walls are muscular, and contract on local stimulation. The veins are not, as a rule, distended with blood to their full potential capacity. The latter is so great that the whole blood of the body can collect within the veins.

The heart and lungs are placed within the thoracic cavity (T), the floor of which is formed by the muscular diaphragm (D); the heart is itself enclosed in a tough inextensile bag, *the pericardium* (P), the function of which is to check over-dilatation of the heart. The pericardium bears to the muscular wall of the heart the same relation as the leather case of a football does to the bag within. In particular, it prevents over-distension of the heart during muscular efforts.

The abdominal organs and blood vessels are encompassed by the muscular wall of the abdomen (A), and may be regarded as enclosed in a sphere of muscle. Above is the dome of the diaphragm (T), and below the basin-like levator ani, closing the outlet of the pelvis; in front are the recti muscles, behind the quadrati lumborum and the spine; while the oblique and transverse muscles complete the wall at either side. The brain is enclosed in a rigid and unyielding box of bone—*the cranium*, while the limbs are encompassed by the extensile and, in health, taut and elastic skin.

The heart's energy is spent in maintaining a pressure of blood in the elastic arteries, and by the difference of pressure in the arteries and veins the blood is kept flowing through the capillaries into the veins. The movements of the body and particularly of respiration help to return the blood from the capillaries and veins back to the heart, valves being set in the veins to direct the blood in this direction. The blood is a viscous fluid and its viscosity varies; it is propelled by a heart which varies both in rate and energy; it circulates through a system of muscular and elastic arteries and veins, which varies in capacity and may alter in elasticity. The width of bed through which it flows varies greatly at different parts of the circuit, and the resistance offered to the moving blood is very much greater in the capillary-sized vessels than in the large arteries and veins. The blood continually varies, both in quantity and in quality, as it effects exchanges through the capillary walls with the tissues. The problems of the circulation are thus far from simple. They resolve themselves mainly into a consideration of (1) the physiology of the heart;

The Action of the Heart.

The permanent position and general arrangements of the heart are described in a separate article, and it is only necessary here to allude to certain points of physiological importance. The substance of the heart is composed of a special kind of muscular tissue which must be regarded as a syncytium in which no distinct and separate cells occur, a complex plexus of branching and anastomosing fibres, forming one functional whole. The fibres are nucleated, have a cross-striated structure and are surrounded by delicate connective tissue sheaths. The cross-striations are due to the primitive fibrils which as in skeletal muscle are differentiated into alternate doubly and singly refracting substances. These fibrils are embedded in a granular nucleated sarcoplasm. Between the bundles of fibres are thin layers of connective tissue containing closely spun networks of capillaries. The muscle of the auricles consists of a circular layer common to both and a deeper layer separate for each chamber. The auriculo-ventricular ring consists of connective tissue surrounding the auriculo-ventricular orifices and separating the auricular from the ventricular muscle with the exception of an important band, the *auriculo-ventricular bundle*. The superficial fibres of the ventricles appear to have origin in the auriculo-ventricular ring, to wind about the heart spirally and to end in the tendons of the papillary muscles or pass up to the ring again on the inner surface of the heart. The middle layers consist of bundles of fibres running more or less circularly round the ventricles.

The greater part of the heart lies free in the pericardial sac. The pericardium is reflected from the wall of the sac on to the wall of the heart and attaches the heart at the point where the venae cavae and aorta leave the sac. This part of the pericardium gives a fixation point to the auricles, for it is attached to the roots of the lungs and thereby to the thoracic wall, to the diaphragm and to the structures at the root of the neck. On opening the chest the normal fulcra for the movements of the auricles are lost, and this renders it difficult to record the exact movements of the heart. The attached part of the heart is called the *base*, and the venous part of the base is the beginning and the arterial part the end of the tube, coiled on itself, from which in the embryo the heart develops. The longitudinal and circular muscle fibres of the ventricles are antagonists. The circular fibres by their contraction tend to lengthen the apex-base diameter, the longitudinal fibres resist this and the two together wring the blood out of the heart. The apex is maintained as a fixed point by this antagonistic action, and thus the longitudinal fibres are enabled to expand the auricles by pulling down the floor of these chambers. This action is important, as it contributes to the filling of the auricles simultaneously with the emptying of the ventricles. Tracings of the jugular pulse give evidence of such action.

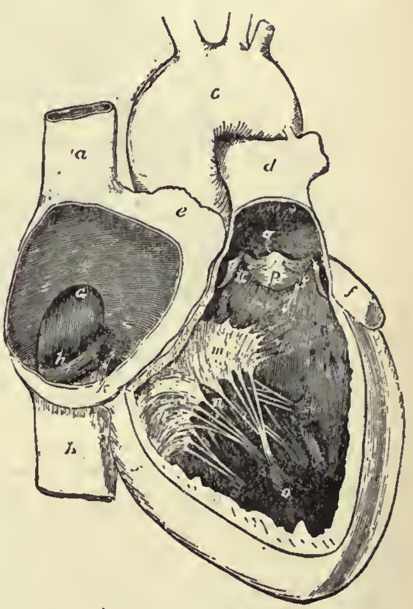

FIG. 6.—Cavities of the Right Side of the Heart. *a*, superior, and *b*, inferior vena cava; *c*, arch of aorta; *d*, pulmonary artery; *e*, right, and *f*, left auricular appendage; *g*, fossa ovalis; *h*, Eustachian valve; *k*, mouth of coronary vein; *l*, *m*, *n*, cusps of the tricuspid valve; *o*, *o*, papillary muscles; *p*, semilunar valve; *q*, corpus Arantii; *r*, lunula.

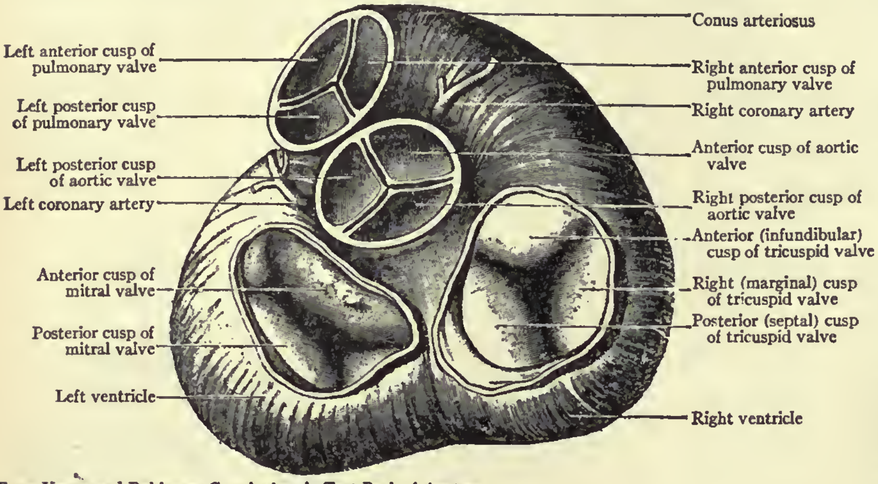
In the case of the auricles the longitudinal musculi pectinati not only help the circular fibres to expel the blood, but draw up the base of the ventricle to meet its load of blood. Thus the base of the ventricular part (or floor of the auricles) is pulled up during auricular systole, and down during ventricular systole. The posterior and upper borders of the left auricle lie against the unyielding structures of the posterior mediastinum, the pulmonary artery and bronchi, the floor and anterior part in contact with the base of the ventricle and ascending aorta respectively. The latter parts alone are free to move during systole. Thus the left ventricular base is drawn up and the aorta back on auricular systole (A. Keith).

The valves of the heart.

As regards the valves of the heart—(1) the tricuspid guards the right auriculo-ventricular opening, and consists of three flaps of fibrous tissue, covered, like all the internal surfaces of the heart, with the smooth shining membrane, the endocardium. The flaps are continuous at their base, forming an annular membrane surrounding the opening. The bicuspid or mitral consists of two cusps and guards the left auriculo-ventricular opening. The under surface and free edge of each cusp of these valves are attached by chordae tendinae to two papillary muscles; these are pillars of muscle which rise up from the inner surface of the ventricles.

The edges of these vaives which come into opposition are exceedingly thin and delicate, while the outer parts, which bear the full systolic pressure of the blood, are tough. The cardiac muscle, by its contraction, limits the size of the auriculo-ventricular orifices and so maintains the competency of the valves. It is the papillary muscles and chordae tendineae which pull down the diaphragm formed by the closed valves (the floor of the auricles), thus expanding the auricles and enabling the valvular as well as the muscular parts of the wall of the ventricles to approach together and wring out the blood. The thin, moist, film-like edges of the valves of the heart come into perfect apposition and prevent all leakage, while the fibrous parts give strength and support. The ventricles are never completely emptied, for some blood remains in contact with the auriculo-ventricular valves up to the end of systole and ensures their closure. Incompetency of the valves may arise when the right heart is greatly dilated. The aortic and pulmonary valves consist of three semilunar, pocket-shaped cusps. A fibrous nodule is placed centrally in the free edge of each cusp, whence numerous tendinous fibres radiate to the attached borders of the cusp. The rest of the free edges which come into apposition are thin and delicate. Opposite the cusps are bulgings of the aortic walls—the sinuses of Valsalva. From the anterior one arises the right coronary artery and from the left postérior, the left coronary artery, these vessels supply the substance of the heart with blood. Eddies formed in the sinuses during the period of systolic output bring the semilunar valves into apposition, so that they close without noise or jar at the moment when the intraventricular becomes less than the aortic pressure. The auriculo-ventricular valves are likewise floated up by eddies, and brought into apposition at the moment the intraventricular pressure surmounts that in the auricles.



From Young and Robinson, Cunningham's *Text-Book of Anatomy.*

FIG. 7.—The Bases of the Ventricles of the Heart, showing the auriculo-ventricular, aortic and pulmonary orifices and their valves.

The heart in size is about equal to the closed fist of a man. The average weight of the heart in the new-born baby is about 24 grms., in the adult 300 grms. The percentage which the heart weight bears to the whole body weight is 0·76 in the new-born and 0·46 in the adult. While the whole body increases in weight 21-fold, the heart increases only 12·74-fold (Vicrordt, Karl, 1818–1884). The average weight of the male and female heart is almost the same.

The average volume of the whole heart is about 270 c.c. The capacity, estimated by filling the heart with wax, is for each auricle about 100–150 c.c., and 150–230 c.c. for each ventricle. There are considerable sources of error in such measurements. The muscle of the left ventricle is about 1·6 cm. in thickness, and of the right ventricle 0·5 cm. The left ventricle has twice the muscular mass of the right. The circumference of the left auriculo-ventricular orifice is about 14·0 cm.; of the right, about 12·5 cm.; of the aortic orifice, 8·0 cm.; of the pulmonary orifice, 9·0 cm. The average diameter of the vena cava superior is about 23 mm.; of the vena cava inferior, 34 mm.; of each of the four pulmonary veins about 13–14 mm.; of the pulmonary artery, 28 mm.; of the aorta, 32 mm.

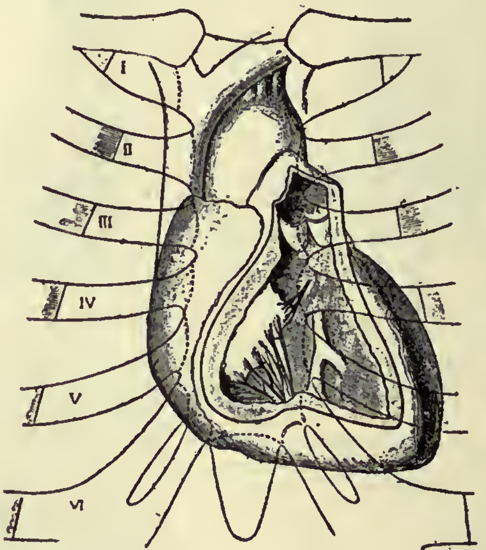
FIG. 8.—Position of the Valves of the Heart in Systole and Diastole.

Modes of examining the living heart.

The physiologist or physician has many means at his disposal of examining the heart's action. By palpation with the hand over the region of the heart, its stroke, the *cardiac impulse*, can be felt. By *auscultation* with the ear directly, or with use of the stethoscope the sounds of the heart can be heard. By *percussion* the anatomical limits of the organ can be defined. The cardiac impulse can be recorded by tambour methods of registration, the heart sounds by means of the microphone and capillary electrometer, while the volume and movements of the heart can be studied with the help of the Röntgen rays

The cardiac impulse.

The impulse is caused by the sudden hardening of the muscular mass of the ventricles against the wall of the thorax. It is synchronous with the beginning of systole. The position at which the impulse is felt varies with changing posture of the body, as different parts of the thorax come in turn in contact with the ventricle. In the supine position it is usually to be felt in the fifth intercostal space $3\frac{1}{2}$ inches from the midsternal line. The chest wall is driven out by the systole only where the heart muscle touches it; at other places it is slightly drawn in. This indrawing is attributed to the expulsion of the blood out of the thorax by the left ventricle. The thorax is a closed cavity and the vacuum therein produced by systolic output into the arteries of the head, limbs and abdomen is filled by (1) the drawing of air into the lungs, (2) the drawing of venous blood into the great veins and right auricle, (3) the slight indrawing of the chest wall. The impulse is recorded by placing a small cup, or receiving tambour, over the spot where it is most evident, and connecting the inside of the cup by a tube to a recording tambour. The cup can be closed by a rubber dam, or an air-tight junction can be effected by pressing it upon the skin. The stroke of the heart is transmitted as a wave of compression to the air within the system of tambours. The recording tambour is brought to write on a drum, moved by clockwork, and covered with a paper smoked with lamp-black. From the record so obtained we can obtain information as to the time relations of the heart-beat, but no accurate information as to its energy or amount of contraction.



From Young and Robinson, Cunningham's *Text-Book of Anatomy.*

FIG. 9.—The Relation of the Heart to the Anterior Wall of the Thorax.

I, II, III, IV, V, VI, the upper six costal cartilages.

Movements of the heart.

The movements of the heart consist of a series of contractions which succeed each other with a certain rhythm. The period of contraction is called the *systole* and that of relaxation the *diastole*. The two auricles contract and relax synchronously, and these movements are followed by the synchronous contraction and relaxation of the ventricles. Finally, there is a short period when the whole heart is in diastole. The whole series of movements is known as the *cardiac* *cycle.* Taking 75 as the average number of heart-beats per minute, each cardiac cycle will occupy ·8 seconds. Of this period

auricular systole occupies	·1 second
auricular diastole occupies	·7 „
ventricular systole occupies	·3 „
ventricular diastole occupies	·5 „

In 1861 Chauveau and Marey obtained direct records of the heart of a horse, and determined the sequence and duration of the events happening in the heart, and measured the endo-cardiac pressure by an instrument termed the cardiac sound. The sound—a two-way tube—was pushed down the jugular vein until the orifice of one tube lay in the right ventricle and of the other in the right auricle. The tubes were connected with recording tambours which wrote on a moving drum covered with smoked paper.

Another tambour was used to record the cardiac impulse. The tracings so obtained (fig. 10) teach us the following facts: (1) The auricular contraction is less sudden than the ventricular, and lasts only a very short time, as indicated by the line *ab*. The ventricle, on the other hand, contracts suddenly and forcibly and remains contracted a considerable time, as shown by the line *c'd'* and by the flat top to the curve which succeeds *d'*. (2) The auricular movement precedes the ventricular, and the latter coincides with the impulse of the apex against the wall of the chest. (3) The contraction of the auricle influences the pressure in the ventricle as shown by the small rise *a'b'*, and that of the ventricle influences the pressure in the auricle somewhat as shown by the waves *cd*. Much labour has been spent in the contrivance of rapidly acting spring pressure gauges, freed as far as possible from inertia, in order to investigate more exactly the changes of intracardiac pressure, which were first described by Chauveau and Marey. As the intraventricular pressure

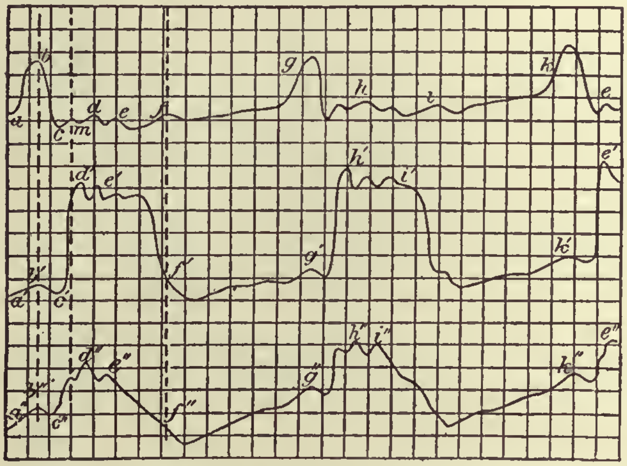


FIG. 10.—Tracings from the Heart of a Horse, by Chauveau and Marey. The upper tracing is from the right auricle, the middle from the right ventricle, and the lowest from the apex of the heart. The horizontal lines represent time, and the vertical amount of pressure. The vertical dotted lines mark coincident points in the three movements. The breadth of one of the small squares represents one-tenth of a second.

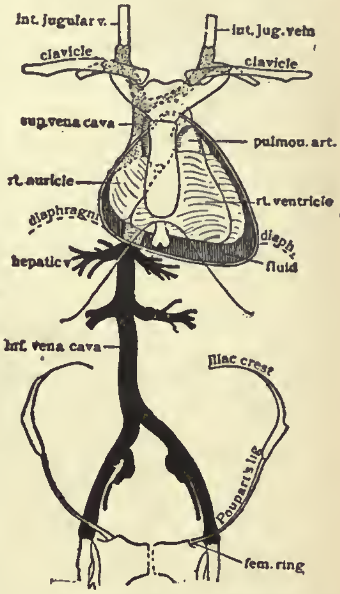
may rise 150 mm. of mercury in one-tenth of a second, it is no easy matter to contrive an instrument which will respond as rapidly and yet yield an accurate result without overshooting the mark. The final result of a most careful inquiry is the confirmation in almost every point of Chauveau and Marey's pressure curves. Karl Hürthle's differential manometer has proved to be an instrument of great value and precision. A double-bored tube cannula is introduced so that one tube reaches the right auricle and the other the right ventricle. In observations on the left side of the heart, one tube is placed in the left ventricle and the other in the aorta, and each of these tubes is brought into connexion with a tambour. The two tambours are placed one on either side of the fulcrum of a lever. This lever works against a light spring, which in its turn sets in motion a writing-style. The style records the pressure changes on a drum covered with smoked paper. By this means there can be recorded the exact moment at which the auricular pressure exceeds that in the ventricle, that is to say, the moment when the auriculo-ventricular valves open; likewise the moment when the ventricular pressure becomes greater than that in the auricles, and the auriculo-ventricular valves shut. Similarly, there can be recorded the moment when the intraventricular pressure exceeds that in the aorta and the semilunar valves open, and the moment at which the diastole of the ventricle begins, when the aortic pressure becomes the greater, and the semilunar valves shut. The smoothness with which the heart works is shown by the fact that neither the opening nor the closing of the valves is marked by any peak or point on the pressure curves.

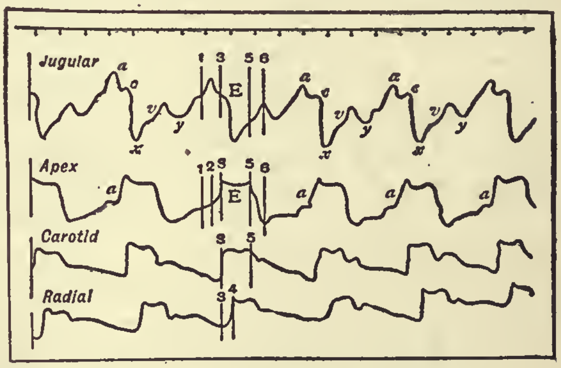
The absence of a mechanism for preventing regurgitation of blood from the auricles of birds and mammals is remarkable, for in fishes, amphibia and reptiles this is effected by valves guarding the sino-auricular junction. In the warm-blooded vertebrata with the appearance of the diaphragm the sinus becomes merged into the right auricle, and the venous cistern formed by the superior and inferior venae cavae, the innominate, iliac, hepatic and renal veins takes the place of the sinus. Six pairs of valves prevent regurgitation from this cistern, viz. those placed in the common femoral, the sub-clavian and jugular veins. The cistern when filled holds some 400 c.c. of blood; in the liver there is some 500 c.c. of blood, and this can be expressed into the cistern by abdominal pressure; in the portal venous system, when distended, another 500 c.c. may be held, which can be expressed through the liver into the cistern. A large volume of blood is thus at the disposal of the heart for it to draw on during diastole. Respiration by the aspirating action of the thorax sucks this blood into the heart, while the inspiratory descent of the diaphragm squeezes the abdominal contents and forces blood from the liver and cistern into the heart. These forces take the place of the sinus and are far more efficient. The intra-abdominal pressure may be raised on bending or straining till it becomes equivalent to the pressure of a column of mercury 80–100 mm. high (Keith). Under such conditions the pericardium prevents the right side of the heart being over-distended with venous blood.



A. Keith, in *Journal of Anatomy and Physiology.*

FIG. 11.—Diagram of the Venous Cistern from which the Heart is filled. The abdominal or infra-diaphragmatic part of the cistern is indicated in black; the thoracic or supra-diaphragmatic is stippled.

With these facts in view, we can now describe the complete course of a cardiac cycle. We will start at the moment when the blood is pouring from the venae cavae and pulmonary veins into the two auricles. The auricles are relaxed and their cavities open into the ventricles by the funnel-shaped apertures formed by the dependent segments of the tricuspid and mitral valves. The blood passes freely through these apertures into the ventricles. The small positive pressure which is always present in the venous cistern (aided by the respiratory forces)

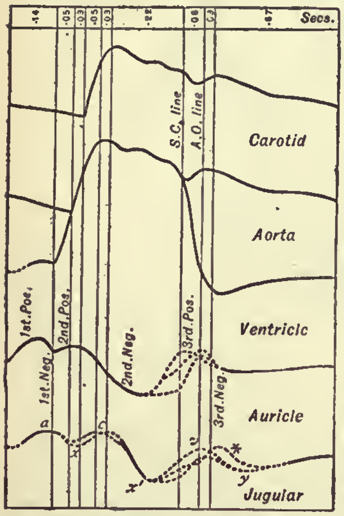


From *Diseases of the Heart*, by James Mackenzie, M.D., by permission.

FIG. 12.—Tracings of the Jugular Pulse Apex Beat, Carotid and Radial Pulses. The perpendicular lines represent the time of the following events:—1, the beginning of the auricular systole; 2, the beginning of ventricular systole; 3, the appearance of the pulse in the carotid; 4, the appearance of the pulse in the radial; 5, the closing of the semilunar valves; 6, the opening of the tricuspid valves.

is at this time filling the right heart, while the positive pressure in the pulmonary veins is filling the left heart. The auricular systole now takes place. The circular muscle bands compress the blood out of the auricles into the ventricles, while the longitudinal bands aid in this and pull up the base of the ventricles to meet the load of blood. As the contraction starts from the mouths of the venae cavae, and sweeps towards the ventricles, there can occur but little regurgitation of blood into the venous cistern, but the cessation of flow into the auricle during its systole does produce a slight rise of pressure in the cistern, as is shown by tracings taken from the jugular pulse. The function of the auricles is to rapidly complete the filling of the ventricles.

The auriculo-ventricular valves are floated up and brought into apposition by eddies set up in the blood which streams into the ventricles, and close without noise or jar at the moment when the intra-ventricular pressure exceeds in the least that in the auricles. The systole of the ventricles immediately following that of the auricles closes the auriculo-ventricular valves, and as the intra-ventricular pressure rises above that in the pulmonary artery and aorta respectively the semilunar valves open and the blood is expelled; these elastic vessels are in their turn expanded by the expulsive force of the heart so as to receive the blood. The papillary muscles, by contracting synchronously with the muscular wall of the ventricles, pull down and flatten the dome-like diaphragm formed by the closed auriculo-ventricular valves, thus shortening the longitudinal diameter of the ventricles, while at the same time they enlarge the auricles and so help to fill these cavities. The outflow of blood from the ventricles is rapid at first. It becomes slower as the big arteries become distended and the pressure of blood rises within them, and ceases finally when the pressure becomes equal to that in the ventricles. As the outflow diminishes the semilunar pockets are filled by eddies of blood, and their thin edges are brought nearer and nearer, until finally they come into apposition. The closure is effected without jar or noise at the moment when the outflow ceases and the ventricles begin to expand. The heart, as a good pump should, works with the least possible jar. During the contraction of the ventricles blood has been pouring from the veins into the auricles, and directly the ventricular systole ceases the auriculo-ventricular valves open, and the blood begins to fill the expanding ventricular cavities. For a brief moment the ventricles remain dilated and at rest, then the auricles contract again, and the cycle of changes, once more, is repeated. During the first period of ventricular systole—the period of rising tension—all the valves are closed and the ventricle is getting up pressure. This period has been measured and is found to occupy ·02″–·04″. The second period is that of systolic output, and lasts about ·2″, that is, from the moment when the semilunar valves open to the moment when they close. The upstroke of the pulse curve taken in the aorta, or in the carotid artery in man, can be taken as marking the moment when the semilunar valves open, while the dicrotic notch on the pulse curve marks their closure. The second sound of the heart occurs immediately after their closure, and can be used to mark the time of this event on the impulse curve.



From *Further Advances in Physiology*, by permission.

FIG 13.—Diagrammatic representation of the Cardiac Cycle and of the Carotid and Jugular Pulses in relation to standard movements. The scale of abscissae is 1 mm. to $\frac{1}{100}$ sec. S.C. = semilunar valve closure; A. O. = auriculo - ventricular valves open. The broken lines indicate those portions of the respective curves over which there is doubt or controversy.

The intra-ventricular pressure curve may rise or fall during the output period according to the state of the peripheral resistance. If the carotid pulse be recorded synchronously with the impulse curve, the time relations can be determined for the human heart. The beginning of the upstroke of the impulse curve marks the beginning of systole, that of the pulse curve marks the opening of the semilunar valves, and the dicrotic notch, which precedes the dicrotic wave, marks the closure of these valves and the end of the output. The first sound of the heart is synchronous with the upstroke of the impulse curve. The maximal systolic pressure exerted by the heart varies with the degree of diastolic filling and with the obstruction to outflow. The heart responds to the latter by a greater output of energy, and this it does with little loss in rapidity of action. The total fluid pressure to which the wall of the heart is submitted rapidly increases as the radii of curvature become greater. Hence the greater energy required of a dilated heart, its tendency to hypertrophy and liability to fail. By its reserve power the heart may throw out three or even six times the volume of the normal output per minute, and may maintain its output when the aortic pressure is twice its normal value.

The maximal and minimal pressures have been accurately recorded in the heart by a manometer fitted with a valve arranged so that either only a rise or a fall of pressure is recorded. In the right ventricle of the dog the maximal pressures recorded equalled 35–62 mm. of mercury, in the left ventricle 114–135 mm., in the auricles 2–20 mm. (Michael Jäger, 1795–1838). A negative pressure, of considerable amount but of very fleeting duration, sometimes occurs in the ventricles at the beginning of diastole. This is produced by the elastic rebound of the fleshy columns of the inner wall of the heart, which become pressed together as the blood is wrung out of the ventricular cavities. The entry of the first few drops of blood from the auricles abolishes this negative pressure, and it has no important influence on the filling of the heart.

The sounds of the heart.

When the ear is applied over the cardiac region of the chest, or a stethoscope is employed, two sounds are heard, the first, heard most intensely over the apex, is a duller and longer sound than the second, which is shorter and sharper and is heard best over the base of the heart. The syllables *lub, dupp* express fairly well the characters of the two sounds, and the accent is on lub when the stethoscope is over the apex, thus—lúb-dupp—lúb-dupp—lúb-dupp, and on the second sound when over the base, thus—lub-dúpp—lub-dúpp—lub-dúpp. The sounds of the heart have been successfully recorded by means of the microphone. Hürthle inserted the microphone in the primary circuit of an E. Du Bois-Reymond induction coil, and placed the nerve of a frog-muscle preparation in the secondary circuit. The muscle, being attached to a lever, recorded its contraction on a revolving drum at the moment when the sound of the heart reached the microphone and closed the primary circuit. A capillary electrometer can be inserted in place of the frog-muscle indicator, and the movements of the electrometer photographed on a sensitized plate moved by clockwork (Willem Einthoven). Each sound gives rise to a succession of vibrations of the mercury meniscus of the capillary electrometer. The first sound is formed of many component tones derived from the sudden tension, and consequent vibration, of the ventricular muscle, and of the auriculo-ventricular valves with their chordae tendineae. The first sound can be resolved by a trained musical ear into two tones, one deep and the other high. The deeper tone alone is heard on the contraction of the excised and bloodless heart, while the higher tone is produced by throwing the auriculo-ventricular valves into tension (John Berry Haycraft). In the cold-blooded animal, such as the turtle, the heart muscle does not become tense rapidly enough to produce a sound (Allen). This sound is not produced by fluid friction as the blood rushes through the arterial orifices, for the velocity of outflow is too small to produce in this way any noise. Nor is it produced by sudden opening of the semilunar valves, for these open quietly and without jar at the moment when the intra-ventricular pressure rises above that in the aorta.

The second sound of the heart is produced by the tension of the semilunar valves in the aorta and pulmonary artery at the moment when the ventricles pass into diastole. These valves close without any jar or shock so soon as the arterial pressures rise to the slightest degree above that in the ventricles. In the next moment the ventricles dilate, and the valves, no longer supported on one side, become taut. The elastic vibrations of the walls of the distended arteries probably share in the production of this sound.

When the sounds and the impulse are recorded together the record shows that the first sound begins about 0·01 sec. before the cardiagram marks the beginning of systole, and for the first 0·06 sec. of its duration this sound is heard only over the apex. Over the base of the heart the first sound is heard just at the time when the semilunar valves open and the output begins. The first sound ceases before the ventricular contraction is over, for it is the sudden tension, not the continuance of contraction, that causes it. The beginning of the second sound marks the sudden tension of the semilunar valves which immediately follows their closure.

For practical purposes it is important to bear in mind what is happening in the heart whilst one listens to its sounds. During the first sound we have (1) contraction of the ventricles, closure of the auriculo-ventricular valves and impulse of the apex against the chest; (2) rushing of the blood into the aortic and pulmonary artery, and filling of the auricles. With the second sound we have closure of the semilunar valves from the elastic recoil of the aorta and pulmonary artery, relaxation of the ventricular walls, opening of the auriculo-ventricular valves so as to allow the passage of blood from auricle to ventricle, and diminished pressure of apex against chest wall. With the long pause there are (1) gradual refilling of the ventricle from the auricle, and (2) contraction of the auricle so as to entirely fill the ventricle. The sound of the tricuspid valve is heard loudest at the junction of the lower right costal cartilages with the sternum, of the mitral over the apex beat, of the aortic semilunar valves in the direction of the aorta where it comes nearest to the surface at the second right costal cartilage, and of the valves of the pulmonary orifice over the third left costal cartilage, to the left and external to the margin of the sternum. The sounds are changed in character by valvular lesion or muscular weakness of the heart, and afford important signs to the physician. Murmurs are produced by eddies setting some part of the membranous walls or valve flaps in vibration.

If a stethoscope be placed over a large artery, a murmur will be heard, caused by the blood rushing through the vessel narrowed by the pressure of the instrument. The fluid escapes into a wider portion of the vessel beyond the point of pressure, and the sound is caused by the eddies set up there throwing the membranous wall of the vessel into vibration. Such a sound is heard over an aneurism. The placental bruit heard during pregnancy is a sound of this kind, arising from pressure on the uterine arteries. In cases of insufficient aortic valves a double blowing murmur may be heard, the first being due to the rush of blood into the vessel, and the second to the regurgitation of the blood back into the ventricle. These murmurs are produced by eddies of blood setting the membranous parts into vibration.

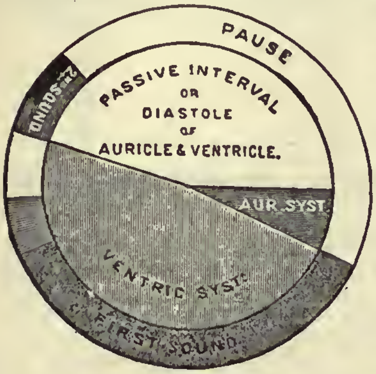


FIG. 14.—Scheme of a Cardiac Cycle. The inner circle shows what events occur in the heart, and the outer the relation of the sounds and silences to these events.

Occasionally a murmur is produced by the displacement of air in the bronchial vessels by the beat of the heart, and may simulate the murmur of aortic incompetence. By placing a stethoscope over the jugular vein on the right above the collar bone a murmur is heard, the *bruit de diable*, particularly if the subject turn his head to the left. This is held to be due to the vibration of the blood in the jugular vein rushing from the dilated to the contracted part. It is more marked during auricular diastole and during inspiration.

In the lower vertebrates, as the frog, the heart is directly nourished by the blood which fills the cavities in its sponge-like structure. In the warm-blooded vertebrates there is a special arrangement of coronary vessels. The two coronary arteries (right and left) originate at the root of the aorta from the sinuses of Valsalva. Their branches penetrate the muscular substance and end in a rich plexus of capillaries. From these arise the radicles of the coronary veins which open into the right auricle by the coronary sinus and other small veins. These openings are valved. The heart in contracting exerts a greater pressure than that of the coronary arteries, and so arrests the flow in these during the height of systole, and squeezes the blood within the coronary capillaries and veins on into the right auricle. On diastole the coronary system fills again. Sudden occlusion of any large part of the coronary arteries produces irregular and inco-ordinate contractions, followed by death of the heart. Gradual occlusion of the coronary arteries by degenerative changes in advanced life is one of the causes of the distressing form of cardiac distress known as angina pectoris.

The nutrition of the heart.

The work of the left ventricle is calculated by the formula $W = VP + mv^2$, where V = volume of blood in c.c. expelled per beat, P = mean pressure in aorta, m = mass of the blood expelled on systole, and v = the velocity imparted to it. The volume of the output has been determined directly by inserting the stromuhr in the ascending aorta (Robert Adolf Tigerstedt), and indirectly by determining (1) how much oxygen is absorbed per minute, (2) the difference in the oxygen content of the arterial and venous blood, (3) the number of heart beats. If 1000 c.c. of oxygen are absorbed from the air breathed in a minute, and the arterial blood contains 10% more oxygen than the venous, it is clear that 100×100 c.c. of blood must have passed through the lungs in that time, and if the heart beat 100 times, the output for each beat would be 100 c.c. From the determinations made on animals the output is calculated for man to be 60–100 c.c. The velocity of the output can be calculated if the volume of the output is known, the duration of the period of output, and the diameter of the aorta. The pressure is measured with a manometer. The velocity is much greater at the orifice than in the aorta, for the blood can flow from the aorta during the whole cardiac cycle, while the whole of it must escape through the orifice into the aorta during the period of output. The work spent on maintaining the velocity is not, however, more than $\frac{1}{10}$ of the whole and is generally neglected in the calculation. The output is not greater than 60–100 c.c. (3 oz.) (Tigerstedt, Nathan Zuntz), and the mean arterial pressure in a healthy man, determined by the sphygmometer, is not more than 110 mm. of mercury (L. Hill). The work of the right heart can be reckoned to be $\frac{1}{3}$ that of the left, for the pressure in the pulmonary artery does not exceed 30 mm. The total work of the heart during the day may be taken as equal to 20,000 kilogr.-metres, and this would be equivalent to 50 calories out of the total 2500 calories which a man takes in as food. A labourer does about 150,000 kilogrm.-metres of external work a day. The work of the heart is increased two or three times over during severe muscular labour. It has been estimated that the heart requires per diem, to maintain its energy, an amount of solid food (water-free) equal to the weight of solids in the heart itself, *i.e.* about 60 grms. of sugar or proteid. 30 c.c. of blood must be circulated per minute through the coronary arteries of a dog to maintain the vigour of the heart.

The work of the heart.

The use of oxygen per grm. of weight per minute is high for the heart. Thus for the whole body of the dog there was used ·017 c.c. per grm. per min., for the heart ·045–·083, and for the active secretory glands ·07–1·0 (Barcroft and Dixon). It has long been known that the heart of frog or tortoise can be kept beating normally for hours after removal from the body, if it is provided with an artificial circulation of blood or a suitable solution of salts. Sydney Ringer worked out the necessary ingredients of this solution to be

The artificial circulation of the heart.

Sodium chloride	0·7 %

Calcium ,,	0·025 %

The excised mammalian heart can be kept beating in the same way provided the nutritive fluid is oxygenated and the heart kept at body temperature. A solution containing one-third defibrinated blood and two-thirds Ringer's salt solution is most suitable. A mammalian heart thus was restored to activity 7 days after death. The beat of the heart of a child was restored 20 hours after death from pneumonia. The excised heart of a cat was kept beating for 4 days. The heart of a monkey was restored after freezing the body of the animal. The nerves of the excised heart retain their action for some time if the nutritive fluid is immediately circulated through the coronary arteries. Thus the heart's action can be conveniently studied when taken from the body of a mammal.

The cause of the heart beat has naturally been one of the most continued objects of inquiry, and the point of view shifts with each advance of our experimental methods, and the wider extension of the inquiry throughout the animal world. H. Allen in 1757 was the first to announce that the activity of the heart is not dependent on its connexion with the nervous system. The excised heart, properly fed, continues to beat. The heart of a dog continued to work effectively and the animal to keep in health for months after division of all the nerves passing to the heart. The heart, it is true, is controlled and influenced constantly by the nervous system—attuned to the general needs of the body—but this control is not essential to life. The above dog, when exercised, became fatigued quickly, owing to the lack of the nervous control of the heart. When in 1848 Robert Remak discovered that groups of nerve cells are contained in the heart of the frog, the causation of the beat was attributed to the activity of these ganglia.

The cause of the heart beat.

Confirmation of this view was found in the experiment of Hermann Stannius which demonstrates that the apex of the heart ceases to beat rhythmically if physiologically separated from the rest of the heart by ligature or momentary application of a clamp. The sinus, on the other hand, which contains ganglion cells, continues its beat as before when separated. Further experiment has shown that the beat of the heart cannot be ascribed to the rhythmic activity of the ganglion cells, which in the mammalian heart lie scattered in the base of the heart, in the neighbourhood of the venous opening and in the auriculo-ventricular groove. That this is so is shown by the fact that every strip of heart muscle, whether free of ganglion cell or not, is capable of rhythmic activity under suitable conditions (Walter Gaskell, 1847– , Theodor Wilhelm Engelmann, Alfred Wm. Porter). The inherent power of rhythmic contraction is most clearly seen in the embryonic heart, for the pulsation of the chick's heart became visible by the 24th to 48th hour of incubation, while the migration of the ganglion cells into the heart from the sympathetic system does not take place until the sixth day (His.). The heart muscle is pervaded by a network of nerve fibrils, and the supporters of the neurogenic theory have had to fall back upon this network as the cause of the beat. The "myogenic" theorists place the causation in the muscle itself.

The pulsating "umbrella" of the jelly-fish is formed of a network of nerve fibril and contractile elements, and this can be excited to contract by irritating any one of the sensory endings of the nervous network which are situated on the edge of the "umbrella." In the manifestation of a "refractory period" the "umbrella" behaves like the heart. Against this view we may cite the experiment of Julius Bernstein (1839), who clamped off the apex of the frog's heart to destroy the physiological continuity, kept the animal alive till the nerve network had degenerated and then found the apex could be mechanically excited to contract. Moreover, skeletal muscle-fibres can be thrown into rhythmic contraction by the application of a suitable solution of salts (Wilhelm Biedermann, 1854), and it is probable that heart muscle is excited to rhythmic activity by such means. At any rate the beat is profoundly affected by varying slightly the nature and percentage of salts supplied in the nutritive fluid. Carlson has recorded experiments upon the heart of the horseshoe crab (*Limulus*) which show that its beat at any rate depends on the integrity of the median nerve (and its ganglion cells) which runs down the heart. On the other hand, Gaskell has shown that any small bridge of heart muscle left connecting the auricle and ventricle of the tortoise heart will transmit the wave of contraction, while if the nerve passing from sinus to ventricle be left, and the muscular connexions entirely severed, no wave passes. In contradistinction to cross-striated muscle, the structural unit of the heart is not also a functional unit, for the heart-cells are, from the earliest stage of development, joined together by branches into networks and bands so as to form one functional whole, and hence excitation of any one part leads to the contraction of the whole. The first part to begin to functionate in the embryo is the venous end, and the waves of contraction passing thence spread over the developing ventricular segment. The muscle-cells of the ventricles are thicker, less sarcoplasmic and more clearly striated than the auricular muscle, which is more embryonic in structure. The contraction lasts longer in the ventricular than in the auricular muscle, while the automatic rhythm not only persists longer in the auricles, but is of greater frequency, as is clearly seen when the cavities of the heart are divided from each other. The venous orifices of the heart are least sensitive to injury, beat longest after death, and are the first to recover after arrest. Owing to the more powerful automatism of the venous extremity, the contraction normally proceeds thence, and. passing as a peristaltic wave over the auricles and ventricles, finally reached the arterial orifices. This peristaltic form of contraction is invariable in all periods of development and in all hearts, both of invertebrate and vertebrate animals. The peristalsis may, with difficulty, be artificially reversed by the application of a powerful rhythmic stimulus to the ventricular end. Antiperistalsis does not, however, take place easily, because the comparatively slow excitatory process in the ventricle has little effect on the auricular muscle. The latter, by initiating more rapid contraction-waves, over-dominates the former. The frequency of the whole heart is accelerated by warming the auricles, while the period of systole is alone shortened on warming the ventricles.

The sequence in the beat of the three chambers of the heart is attributed by Gaskell to the delay that occurs in the excitatory wave passing through the muscular connexions in the sino-auricular and auriculo-ventricular junctions. He showed that such delay could be imitated by moderately clamping a strip of heart muscle; the compressed part transmitted the wave less readily, so that the part above and below the clamp contracted in sequence.

In the mammalian heart there has recently been discovered a remarkable remnant of primitive fibres persisting in the neighbourhood of the venous orifices (representing the sinus). These fibres are in close connexion with the vagus and sympathetic nerves, and form the sino-auricular node of A. Keith and Martin Flack. If this node is squeezed by a clamp, it prevents the effect of excitation of the vagus reaching the heart. The auricle and ventricles of the mammalian heart are connected through the septum by a remarkable bundle of muscle fibres which is believed to convey the excitatory wave from the one cavity to the other. The root of this auriculo-ventricular bundle lies in the right auricle, the main part is buried in the inter-ventricular septum; its branches and twigs are distributed to all parts of either ventricle; the papillary muscles and fleshy columns, in particular, receive a direct supply. The muscle fibres are of a peculiar type, known as the cells of Purkinje. By this bundle it is believed every part of the ventricle is brought into synchronous contraction. To its degeneration has been ascribed certain cases of disturbed cardiac rhythm, when the ventricle no longer follows the sequence of auricle. The evidence of such degeneration is, at present, not convincing.

(After A. Keith, in *Journal of Anatomy and Physiology*.)

The electrical change of the heart.

The contraction of the heart, like that of other muscle, is accompanied by an electrical change. The part in contraction is at different potential to the part at rest. Thus an electrical wave accompanies the wave of contraction. This has been studied by means of the capillary, or the string, electrometer (Sir John Scott Burdon-Sanderson and Page, Einthoven, Gotch). The photographic records obtained with these instruments afford us a most beautiful method of recording the rhythm of normal and abnormal hearts in man, for they can be obtained by connecting the right hand and left foot of a patient with the instrument. Einthoven, by making use of the telephone wires, recorded in his laboratory the electrical changes of the hearts of patients seated in a hospital 2 m. away.

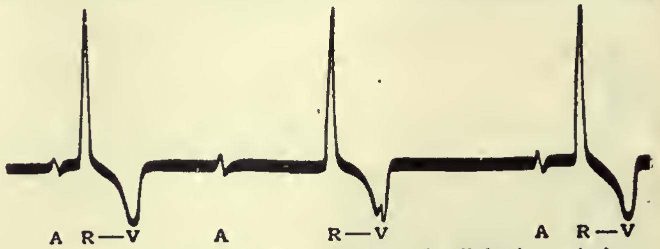

FIG. 16.—Electrical Changes of Heart. A, diphasic variation of auricle; R—V, diphasic variation of ventricle. R = base negative; V = apex negative to base. After auricular contraction the ventricular is delayed—an example of arhythmia. (Einthoven.) The string galvanometer is the best method for elucidating disorders of cardiac rhythm.

The heart during the period of systole is refractive to artificial excitation, but its susceptibility returns with diastole. The force and amplitude of any cardiac contraction depend on the previous activity of the heart and on such physical conditions as the degree of diastolic filling, the resistance to systolic outflow, temperature, &c., but are independent of the strength of the artificial stimulus so long as the latter is efficient. Owing to the refractory period, the slow rate of contraction and the independence of the amplitude of contraction on the strength of stimulus, the heart under ordinary conditions cannot be thrown, by rapidly repeated excitation, into a complete state of tetanic spasm. The refractory period can be shortened by heat (40° C.), or by calcium and sodium salts until tetanus is obtainable. The cardiac muscle is rich in sarcoplasm, and on this depends its power of slow, sustained contraction. The heart-muscle, besides rhythmically contracting, possesses "tone," and this tone varies with the conditions of metabolism, temperature, &c. Chloroform, for example, produces a soft dilated, strychnine, adrenalin or ammonia a tonically contracted heart. The mammalian heart ceases to beat at temperatures below 7° C. and above 44° C., and passes into "heat rigor" at 45° C.

The Cardiac Nerves.—In 1845 the brothers Weber made the astonishing discovery that the vagus nerve, when excited, slowed or even arrested the action of the heart. This was the first proof of the existence of inhibitory nerves. The cardiac inhibitory nerves have since been found in all classes of vertebrates and in many invertebrates. Some years later v. Beyeld (1862) and Moses and Il'ya Cyon (1843–) discovered the existence of nerve fibres which, when excited, augmented and accelerated the beat of the heart. These nerves arise from 1–5 thoracic anterior spinal nerve roots and have their "cell stations" in the first thoracic and inferior cervical ganglia, whence they pass to the heart partly in company with the cardiac branches of the vagus, and partly as separate twigs. The vagus cardiac fibres arise by the middle of the lowermost group of vagus roots, and have their cell-stations in the ganglion cells of the heart. These ganglion cells lie chiefly in the sub-pericardial tissue in the posterior wall of the auricles between and around the orifices of the venae cavae and pulmonary veins and between the aorta and pulmonary artery. The minute structure of these ganglia and the terminations of the nerves have been studied particularly by Dogiel. The inhibitory fibres arise from a centre in the spinal bulb which is in tonic action and constantly bridles the heart's action. When the vagi are divided the frequency of the heart increases and the blood pressure rises. The vagus centre is reflexly excited by the inhalation of chloroform, ammonia or other vapour irritant to the air passages, also by the want of oxygen in the blood in asphyxia. It may be excited by irritation of the abdominal nerves, *e.g.* a blow on the abdomen, and by increased pressure in the cerebral vessels. The acceleratory and augmenting fibres

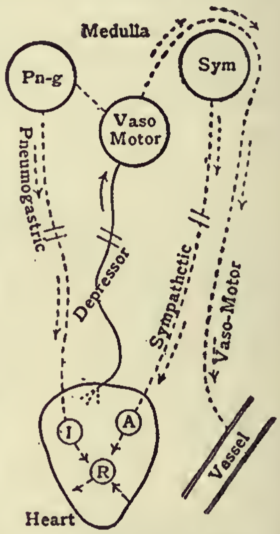

FIG. 17.—The origins of pneumogastric and vasomotor systems are in medulla, that of the sympathetic in upper portion of cord. The arrows indicate direction of nerve currents. In the heart R represents a reflex centre, I an inhibitory centre and A an accelerating centre.

likewise have their centre in the spinal bulb, and are in tonic action, antagonizing more or less the action of the vagal centre. The vagus nerve works directly on the cardiac muscle, and produces some change (signalized by a positive variation in the electrical state of the heart) which results in a depression of the excitability, the conductivity, the force and the frequency of the heart. After the vagal arrest the heart beats more forcibly, owing, it is thought, to the greater accumulation of contractile material during the period of rest. The converse of all these effects occurs on stimulation of the accelerator nerves. Excitation of these nerves may excite to renewed efforts an excised heart which has just ceased to beat after withdrawal of the supply of nutritive solution. Hence it is thought by some that the accelerator nerves tonically exert a sustaining influence on the heart.

FIG. 18.—B, arterial blood pressure. K, record of volume of kidney. Inhibition of heart on faradizing vagus nerve.

The alkaloid atropin paralyses the vagal nerve endings in the heart, while nicotine paralyses the ganglion cells. Muscarin obtained from poisonous fungi slows and finally arrests the heart. Adrenalin, the active principle of the medulla of the supra-renal glands, augments its power. Chloroform depresses it and in poisonous dose throws the heart into paralytic dilatation. A great many of the cardiac vagal fibres convey impulse to the spinal bulb (centripetal), and reflexly influence the heart frequency, the breathing and the tonus of the blood vessels. In particular certain fibres, termed *depressor* (discovered by Ludwig and Cyon, 1866), cause dilatation of the arterioles and a fall of arterial pressure by inhibiting the tonic action of the vaso-motor centre in the spinal bulb. The depressor fibres arise from the root of the aorta, and over-distension of this part excites them, as evidenced not only by the above effect, but also by the electrical variation (action current) which has been observed passing up the depressor nerve. Sensory impressions originating in the heart do not as a rule enter into consciousness. They are carried by the cardiac nerves to the sympathetic ganglia, and thence to the upper thoracic region of the spinal cord, where they come into relation with the sensory nerves from the pectoral region, upper limb, shoulder, neck and head. The impressions are not felt in the heart, but referred to these sensory cutaneous nerves. Thus cardiac pain is felt in the chest wall and upper limbs and particularly on the left side. The function of the cardiac nerves is to co-ordinate the beat of the heart with the needs of the body and to co-ordinate the functions of other organs with the needs of the heart. For example, an undue rise of arterial pressure, induced, let us say, by compression of the abdomen, excites the centre of the vagus and produces slowing of the heart and a consequent lowering of arterial pressure. The heart of a mammal, however, continues to functionate after a section of all the branches of the cardiac plexus has been made, so that the nervous control and co-ordination of the heart are not absolutely essential to the continuance of life.

Certain physical factors concerning the circulation.

Water flowing through a tube from a constant head of pressure encounters a resistance occasioned by the friction of the moving water particles against each other and against the stationary layer that wets the wall of the tube. Part of the potential energy of the head of pressure is spent in endowing the fluid with kinetic energy, the greater part in overcoming this resistance is rubbed down into heat. The narrower the tube is made, the greater the friction, until finally the flow ceases, the total energy being then insufficient to overcome the resistance.

The resistance may be measured at any point in the tube by inserting a side tube in the vertical position. The water rises to a certain height in the side tube, indicating the head of pressure spent in overcoming the resistance between the point of measurement and the orifice. If the lower end of the side tube is bent thus ⅃ and inserted so that its orifice faces the stream, the water will rise higher than it did in the first case. The extra rise indicates the head of pressure spent in maintaining the velocity of flow. Such a method has been used to measure the velocity of flow in the vascular system (Napoleon Cybulski). When a stream of water is transmitted intermittently by the frequent strokes of a pump through a long elastic rubber tube, the fluid does not issue in jets as it would in the case of a rigid tube, but flows out continuously. The elastic tube is distended by the force of the pump, and its elasticity maintains the outflow between the strokes. The continuous outflow here depends on the elasticity of the tube and the resistance to flow.

In the vascular system an area of vessels of capillary size is placed between the large arteries and veins. This area opposes a great resistance to flow. The arteries also are extensile elastic tubes. The effect of the peripheral resistance, as it is called, is to raise the pressure on the arterial side and lower it on the venous. The resistance to flow is situated chiefly, not in the capillaries, but in the small arteries, where the velocity is high; for "skin friction"—that is, the friction of the moving concentric layers of blood against one another and against the layer which wets the wall of these blood vessels is proportional to the surface area and to the viscosity of the blood—is nearly proportional to the square of the velocity of flow, and is inversely proportional to the sectional area of the vessels. Owing to the resistance to the capillary outflow, the large arteries are expanded by each systolic output of the heart, and the elasticity of their walls comes into play, causing the outflow to continue during the succeeding diastole of the heart. The conditions are such that the intermittent flow from the heart is converted into a continuous flow through the capillaries. If the arteries were rigid tubes, it would be necessary for the heart to force on the whole column of blood at one and the same time; but, owing to the elasticity of these vessels, the heart is saved from such a prolonged and jarring strain, and can pass into diastolic rest, leaving the elasticity of the distended arteries to maintain the flow. As a result of disease, the elastic tissue may degenerate and the arteries become rigid. Besides the saving of heart-strain, there are other advantages in the elasticity of the arteries. It has been found that an intermittently acting pump maintains a greater outflow through an elastic than through a rigid tube; that is to say, if the tubes be of equal bore. The four chief factors which co-operate in producing the conditions of pressure and velocity in the vascular system are—(1) the heart-beat, (2) the peripheral resistance, (3) the elasticity of the arteries, (4) the quantity of blood in the system. Suppose the body to be in the horizontal position and the vascular system to be brought to rest by, say, excitation of the vagus nerve and arrest of the heart. A sufficiency of blood to distend it collects within the venous cistern. The arterial system, owing to its elasticity and contractility, empties. If the heart now begin to beat, blood is taken from the venous system and is driven into the arterial system. The arteries receive more blood than can escape through the capillary vessels, and the arterial side of the system becomes distended, until equilibrium is reached, and as much blood escapes into the venous side per unit of time as is delivered by the heart. The flow in the capillaries and veins has now become a constant one and if the side pressure be measured it will be found to fall from the arteries to the capillaries, and from the capillaries to the venae cavae. In the large arteries there is a large side pressure which rises and falls with the pulses of the heart. The pulse waves spread out over a wider and wider area as the arteries branch. They finally die away in the arterioles. An increase or decrease in the energy of the heart-beat will increase or decrease respectively the velocity of flow and pressure of the blood. An increase or decrease in the total width of the arterioles respectively will lessen or raise the resistance; increase or decrease the velocity; lower or raise the blood pressure. A loss of blood, other conditions remaining the same, would cause a decrease in pressure and velocity. As a matter of fact, such a loss is compensated for by the adjustability of the vascular system. Tissue lymph passes from the tissues into the blood, and the blood vessels of the limbs and abdomen constrict, and thus the pressure is kept up, and an efficient circulation maintained through the brain, lungs and coronary vessels of the heart.

Structure of the blood vessels.

The whole vascular system is lined within by a layer of flattened cells, the *endothelium*; each cell is exceedingly thin and cemented to its fellows by a wavy border of an interstitial protoplasmic substance. The endothelium affords a smooth surface along which the blood can flow with ease. Outside it there exists in the arteries and veins a middle and an external coat. The middle coat varies greatly in thickness and contains most of the non-striated muscle-cells, which in the smaller arteries and arterioles form a particularly well developed band. In the larger arteries (fig. 19) a great deal of yellow elastic tissue, together with some white, fibrous tissue, pervades the middle coat. At the inner and outer border of this coat the elastic fibres fuse to form an internal and external fenestrated membrane. This coat endows the arteries with extensibility, elasticity and contractility. The outside coat consists mostly of white fibrous tissue and not only protects the arteries, but by its rigidity prevents over-distension. In the veins (fig. 20), where the middle coat is somewhat thinner and contains less elastic tissue, the outer coat consists mostly of muscle-fibres. The valves of the veins are formed of fibrous and elastic tissue covered with endothelium. As the arterioles branch into capillaries the muscular and elastic elements become less and less, until in the capillaries themselves there is left only the layer of endothelium, supported by some stellate connective tissue cells. The capillaries form networks which accommodate themselves to the structure of the organs, *e.g.* longitudinal networks in muscle, loops in the papillae of the skin, close-meshed networks round the alveoli of glands, cells of liver, &c. In the liver the blood penetrates into the substance of the liver-cells. As the capillaries join together to form the vennules, muscle-fibres again appear and coat the walls of the latter. The veins have a greater capacity than the arteries. Blood vessels, the vasa vasorum, supply the walls of the large vessels with nutrition.

FIG. 21.—Structure of Blood Vessels (diagrammatic). A¹, capillary—with simple endothelial walls. A², larger capillary—with connective tissue sheath, "adventitia capillaris"; B, capillary arteriole—showing muscle cells of middle coat, few and scattered; C, artery—muscular elements of the tunica media forming a continuous layer.

The vaso-motor nerves end in a plexus of fibrils among the muscle-fibres. Ganglion cells occupy the larger nodes of the nerve plexus. The ends of a torn artery retract, coil up within the external coat and prevent haemorrhage. The arteries contract when mechanically irritated and remain contracted for a long time after excision. They tend to contract when submitted to increased blood pressure. The capillaries cannot contract of themselves, but their lumen can be widened or narrowed by the varying contractility or turgidity of the tissues in which they run.

The arteries successfully withstand elastic strain of the pulse 70 times a minute throughout the years of a long life. It has proved possible to stitch divided arteries and veins together so perfectly that the circulation can continue through them. A kidney has thus been successfully transplanted from one dog to another, and has continued to functionate normally.

The elastic coefficients of the several layers of the coat of an artery increase from within out, and thus great strength is obtained with the use of a small amount of material. Over-expansion of the arteries is checked by an external coat of inextensible connective tissue. The elasticity of a healthy artery is almost perfect, while the breaking strain is very great and far above that exerted by the blood pressure. The small arteries and arterioles are essentially muscular tubes, and can, under the influence of the central nervous system, vary considerably in diameter.

The pulse. By the expulsion of the blood at each systole the walls of the aorta are suddenly distended. From the aorta a wave of distension ripples down the walls of the arteries. This wave of distension is called the pulse. As the pulse is distributed over an ever-widening field its energy is expended and it disappears finally in the arterioles. From a wounded artery the blood flows out in pulses, from a wounded vein continuously. To stop the haemorrhage the ligature must be applied between the wound and the heart in the case of the artery, and between the peripheral parts and the wound in the case of the vein. The pulse travels about 20 times as fast as the blood flows in the arteries (7–8 metres per second). By feeling the pulse we can tell whether the heart-beat is frequent, quick, strong, regular, &c., and whether the wall of the artery is normal and the pressure in the arteries high or low. Frequency expresses the number per minute, quickness the duration of a single beat. The pulse is a most important guide to the physician. The pulse can be registered graphically by means of a sphygmograph. A lever rests on the radial artery and transmits the pulse to a system of levers which magnifies the movement and records it on a smoked surface moved by clockwork.

In such a record, or sphygmograph, the upstroke corresponds to systolic output of the left ventricle, marking the opening of the aortic valves, and the pouring of the blood into the arteries.

The downstroke represents the time during which the blood is flowing out of the arteries into the capillaries. There are subsidiary waves on the downstroke. The chief of these is called the dicrotic wave, the notch preceding which marks the closure of the semilunar valves. The dicrotic wave is caused by the jerk back of the blood towards the heart when the outflow ceases, and is most manifest when the systole is short and sharp and the output of blood from the arterioles rapid, in other words when the heart-beat is strong, the systolic pressure high and the diastolic pressure low. A smaller wave, predicrotic, preceding this occurs during the period of output and sometimes is placed on the ascending limb of the pulse curve. This occurs when the peripheral resistance is great, and the pulse is then termed anacrotic.

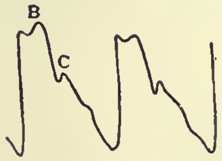

FIG. 22.— Anacrotic Pulse.

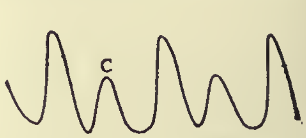

FIG. 23.—Dicrotic Pulse.

FIG. 24.—Normal Pulse, and Time Tracing in $\frac{1}{10}$ sec.
A, Primary wave. C, Dicrotic wave.
B, Predicrotic wave. D, Post-dicrotic wave.

The form of these waves is modified by the pressure of application of the sphygmograph, and by instrumental errors; and we have no scale by which we can measure the blood pressure in sphygmograph tracings. To do this another instrument, the sphygmomanometer, is employed.

The pulse may pass through the arterioles and reach the capillaries when the arterioles are dilated or when the capillaries are only filled at each systole, as may be seen in the pink of the nail when the arm is held above the head, and in cases of aortic regurgitation.

A venous pulse may be recorded in the jugular vein; it exhibits oscillations synchronous with auricular and ventricular systole, and affords us important information in certain cases of heart disease. The normal average pulse rate is 72 per minute, in woman about 80; but individual variations from 40–100 have been observed consistent with health. In the newborn the pulse beats on the average 130–140 times a minute; in a one-year-old child 120–130; three years 100; ten years 90; fifteen years 70–75. Active muscular exercise may increase the pulse rate to 130. Nervous excitement, extreme debility and rise of body temperature also increase it markedly. The pulse is more frequent when one stands than when one sits, or lies down, and this is especially so in states of debility. The taking of food, especially hot food, increases it. By placing tambours on, say, the carotid and radial arteries and recording the two pulses synchronously, it has been found that the pulse occurs later, the further the seat of observation is from the heart. The velocity with which the pulse wave travels down the arteries has been determined thus. It is about 7–8 metres per second. The wave length of the pulse is obtained by multiplying the duration of the inflow of blood into the aorta by the velocity of the pulse wave. It is about 3 metres. As the return of venous blood and pulmonary circulation is favoured during inspiration so that the output of the left ventricle during the first part of inspiration is lessened and subsequently increased, the sphygmograph reveals respiratory oscillations; the whole line of the tracing falls during the first part of inspiration and rises subsequently.

The capillary circulation. The circulation in the capillaries may be studied by placing under the microscope a transparent membrane such as the web of the frog's foot, tail of tadpole, wing of bat, &c. By a special illumination one may see the shadow of the blood corpuscles moving through the retinal vessels of one's own eye, and even calculate the velocity of flow. The diameter of the smaller capillaries is such as to permit the passage of the red blood corpuscles in single file only; their length is about $\frac{1}{50}$th of an inch. The endothelial cells confine the blood from direct contact with the tissue lymph and so prevent its coagulation, but allow and regulate the exchange of material between the blood and lymph. This exchange is regulated by the vital activity of the cells, and does not follow such laws as pertain to filtration and diffusion through dead membranes. There is evidence to show that the cells of the hepatic capillaries are capable of protoplasmic movement and of phagocytosis. The pressure in the capillaries stands in closer relationship to that in the veins than to that in the arteries; for example, a rise of pressure in the venae cavae, other things remaining the same, raises the pressure in the hepatic capillaries to a like amount, while a rise of pressure in the aorta does not, for most of the arterial pressure is spent in overcoming the peripheral resistance. The filling of the capillaries in the skin varies greatly with temperature, posture, &c. When the hand is cold the arterioles are so constricted that blood only passes through the wider and more direct capillaries. As the skin becomes warm it flushes, the arterioles dilating and all the capillary networks becoming filled with blood. Muscular movements express the blood out of the capillaries, as may be seen by the blanching of the skin which occurs on clenching the hand. Raising the hand blanches, and lowering it congests the capillaries. The pressure and velocity in the capillaries thus constantly vary, owing to alterations in hydrostatic pressure, the pressure of the body against external objects, the contraction of the muscles, and the contraction of the arterioles. It is not possible therefore to set any definite figure to the capillary pressure or velocity. In the frog's web, with the foot confined and at rest, the velocity is about 1 mm. per second. We continually make slight movements to counteract the hydrostatic effect and prevent the congestion of blood in the capillaries of lower parts of the body. It is this tendency to congestion which makes it so difficult to stand absolutely motionless for any length of time. The red corpuscles, being the heavier, occupy the axis, and the white corpuscles the peripheral layer of the capillary stream. If an irritant is placed on the membrane it will be observed that the capillaries become wider and crowded with corpuscles, the flow slackening and finally becoming arrested owing to the passing out of the plasma through the damaged capillary wall. The white corpuscles creep out between the endothelial cells into the tissues. Such are the first phenomena of inflammation. After obstruction of an artery collateral pathways are in most parts rapidly formed, for the anastomatic capillaries, stimulated by the increased blood flow, develop into arterioles and arteries.

The flow in the veins. Numerous anastomoses exist between the veins, so that if the flow of blood be obstructed in one direction it readily finds a passage in another. Muscular movement, alterations of posture and respiratory movements particularly forward the venous circulation. The barber's pole of the barber surgeon was grasped to increase the flow in the old blood-letting days. The valves in the veins allow the blood to be forced only towards the heart. The pressure in the veins varies according to the hydrostatic pressure of the blood column above the point of measurement. In the horizontal position, when this factor is almost eliminated, the pressure in the large veins is about equal to 5–10 mm. of mercury, and even may become negative on taking a deep inspiration. There thus arises the danger of air being sucked into a wounded jugular vein. If air does thus gain entry it may fatally obstruct the circulation.

The venous circulation is impeded by (1) a lessening of heart power, (2) valvular defects, such as incompetence or narrowing of the orifice which they guard, (3) obstruction to the filling of the heart, as in cases of pericardial effusion, (4) obstruction of the pulmonary circulation as in coughing, by pleuritic effusion, &c. The results of venous congestion are a less efficient arterial circulation, a dusky appearance of the skin, a fall of cutaneous temperature, and an effusion of fluid into the tissue spaces producing oedema and dropsy. This last effect is not due to increased capillary pressure producing increased transudation as has been supposed, for no such increase in venous and capillary pressure persists under the conditions. It is due to the altered nutrition of the capillary endothelium and the tissues, which results from the deficient circulation.

If for any reason the left ventricle fail to maintain its full systolic output, it ceases to receive the full auricular input, and in consequence the pulmonary vessels congest. This tells back on the right heart, and the right ventricle is unable to empty itself into the congested pulmonary vessels, and this in its turn leads to venous congestion. The final result of any obstruction thus is a pooling of the blood in the venous cistern. Dyspnoea results from cardiac insufficiency. It is excited by the increased venosity of the blood acting on the respiratory centre. Both excess of carbon dioxide and deficiency of oxygen excite this centre. The increased respiratory movements aid the circulation.

The venous side of the vascular system, owing to the great size of the veins, has a large potential capacity, while many of the capillaries in each organ are empty and collapsed, except at those periods of vaso-dilatation and hyperaemia which accompany extreme activity of function. The vascular system cannot be regarded as a closed system, for the blood-plasma, whenever the capillary pressure is increased, transudes through the capillary wall into the tissue-spaces and enters the lymphatics. Thus, if fluid be transfused into the circulatory system, it not only collects in the capacious reservoirs of the veins and capillaries—especially in the lungs, liver and abdominal organs—but leaks into the tissue-spaces. Hence the pressure in the vascular system cannot be raised above the normal for any length of time by the injection of even enormous quantities of fluid. The lymphatics of tissue-spaces must be regarded as part of the vascular system. There is a constant give and take between the blood-plasma and the tissue lymph. If the fluid part of the blood be increased, then the capillary transudation becomes greater, and the excess of fluid is excreted from the kidneys and glands of the alimentary canal. If the fluid part of the blood diminish, then fluid passes from the tissue-spaces into the blood, and the sensation of thirst arises, and more drink is taken.

Haemorrhage and transfusion. The circulation may be greatly aided by the transfusion of salt solution (0·8 %) or blood after severe hemorrhage, or in states of surgical shock. Only the blood of man must be used. The direct giving of blood by connecting the radial artery of a relation to the median vein of a patient has been used as a means of effecting restoration. Blood may be withdrawn from the system slowly to the extent of 4 %, rapidly to the extent of 2 % of the bodyweight, without lowering the arterial pressure, owing to the compensatory contraction of the arterioles and the rapid absorption of fluid from the tissues into the blood. The withdrawal of the tissue-lymph excites extreme thirst and the great need for water which occurs after severe hemorrhage. About 75 % by weight of the tissues, excluding fat and bone, consists of water. The quantity of blood in the body is about $\frac{1}{20}$th of the body weight. That of tissue-lymph is unknown, but it must be considerable, probably greater than that of the blood. The lymphatics drain off the excess of fluid which transudes from the capillaries, and finally return it to the vascular system. The interchange between tissue, blood and lymph depends on the forces of the living cells, which are as yet far from complete elucidation.

The velocity of blood flow. We may define the velocity of the blood at any point in a vessel as the length of the column of blood flowing by that point in a second. In the case of a tube, supplied by a constant head of pressure, we can divide the tube and measure the outflow per second; knowing the volume of this, and the cross area of the artery, we can determine the length of the column. This kind of experiment cannot be done on the living animal, because the opening of the vessel alters the resistance to flow, and the loss of blood also changes the physiological conditions. To determine the velocity other means must be devised. Ludwig invented an instrument called the stromuhr, consisting of two bulbs mounted on a rotating platform pierced with two holes. One bulb is filled with oil—the other with blood. The bulbs are connected together by a tube at their upper end, and the lower end of the one full of oil is brought over the hole in the platform. The central end of the artery is connected to the same hole and the peripheral end to the other, over which stands the bulb full of blood. The blood being allowed to flow displaces the oil out of the one bulb into the other; directly this happens, the bulbs are rotated and the one full of oil is again brought over the central end of the artery. The number of rotations per minute is counted, and the volume of the bulb being known we obtain the volume of blood that passes through the instrument per minute. In another instrument, the haemodromograph of Chauveau, there is inserted into the artery a ⊥ tube in which hangs a small pendulum; the stem of the pendulum passing through a rubber dam which closes the vertical limb of the tube. The pendulum is deflected by the flow, and the greater the velocity the greater the deflection. The deflection can be recorded by connecting the free end of the pendulum to a tambour arrangement. This instrument allows us to record and measure the variations of velocity during systole and diastole of the heart, but it can only be used in the vessels of large animals. Still other methods have been employed by Cybulski and Stewart. The general relations of the velocity of the blood in the arteries, capillaries and veins is expressed by the curve shown in fig. 26. The velocity in the large arteries may reach 500 mm. per second

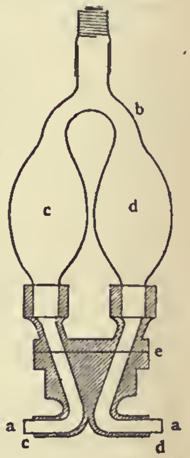

FIG. 25.—Ludwig's Stromuhr.

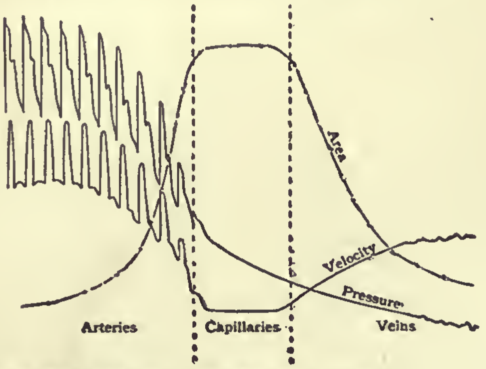
in systole and fall to 150 mm. in diastole. The smaller the artery the less is this difference and the more uniform the rate of flow.



From Allchin's *Manual of Medicine*, by permission of Macmillan & Co. Ltd.

FIG. 26.—Diagram showing General Relations of the Velocity of the Blood in the Arteries, Capillaries and Veins.

The flow in the large veins is approximately equal to that in the large arteries. In the jugular vein of a dog the mean velocity was found to be 225 mm. and in the carotid 260 mm. per second. The velocity in the capillaries has been measured by direct observation with the microscope. It is very small, *e.g.* 0·5–1 mm. per second. The variation of velocity in different parts of the vascular system is explained by the difference in width of bed through which the stream flows. The vascular system may be compared to a stream which on entering a field is led into a multitude of irrigation channels, the sum of the cross sections of all the channels being far greater than that of the stream. The channels unite together again and leave the field as one stream. If the flow proceeds uniformly for any given unit of time, the same volume must flow through any cross section of the system. Thus the greatest velocity is where the total bed is narrowest, and slowest where the bed widens to the dimensions of a lake.

The time necessary for a complete circulation.

The blood in leaving the heart may take a short circuit through the coronary system of the heart and so back to the right heart, or it may take a long and devious course to the toes and back, or through the intestinal capillaries, portal system and hepatic capillaries. It is obvious, then, that the time any two particles of blood take to complete the circuit may be widely different. Experiments have been made to determine how rapidly any substance, like a poison, which enters the blood may be distributed over the body. A salt such as potassium ferrocyanide is injected into the jugular vein, and the blood collected in successive samples at seconds of time from the opposite jugular vein. These samples are tested for the presence of the salt, or a strong solution of methylene blue is injected into the jugular vein, and the moment determined with a stop-watch when the blue colour appears in the carotid artery.

The velocity of flow also can be determined in any organ by injecting salt solution into an artery, and observing, with the aid of a Wheatstone's bridge arrangement, the galvanometric change in electrical resistance which occurs in the corresponding vein when the salt solution reaches it. The moment of injection and that of the alteration in resistance are observed with a stop-watch (Stewart).

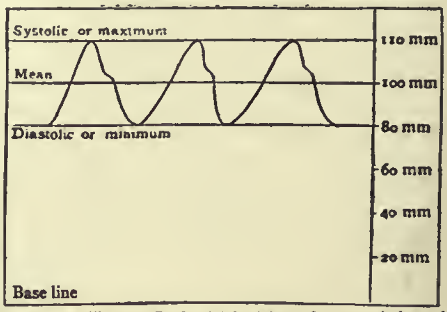
It has been determined that the blood travelling fastest can complete the circuit in about the time occupied by 25 to 30 heart-beats, say in 20 to 30 seconds; a result which shows how rapidly methods must be taken to prevent the absorption of poisons—for example, snake-poison. The blood travelling fastest in the pulmonary circuit occupies only about one-fifth of the time spent by that in the systemic circuit. That some of the blood takes a very long time to return to the heart is shown by the long time it takes to wash the vascular system free of blood by the injection of salt solution.

The pressure relation in the vascular system.

That the blood is under different pressure in the various parts of the system has long been known. From a divided artery the blood flows out in forcible spurts, while from a vein it flows out continuously and with little force. It takes very little pressure of the fingers to blanch the capillaries of the skin, but an appreciable amount to obliterate the radial artery.

Stephen Hales (1733) was the first to measure the blood pressure. He inserted a brass tube into the femoral vein of a horse and connected it to a long glass tube held vertically, using the trachea of a goose as a flexible tube, and found the blood rose to the height of 8 ft., oscillated there with each heart-beat, and rose and fell somewhat with inspiration and expiration. In the vein he found the pressure to be only about 12 in. Poiseuille (1828) adapted to the same purpose the mercurial manometer, a U-shaped tube containing mercury, which, being 13·5 times heavier than blood, allowed the manometer to be brought to a convenient height. The introduction of rubber tubing for the connexions made the method of inquiry comparatively simple. The tubing connecting the arterial cannula and the manometer was filled with a suitable fluid to prevent coagulation of the blood; also to prevent more than a trace of blood entering the connexions. A saturated solution of sodium sulphate, or a 1% solution of sodium citrate, may be employed for this purpose. Ludwig (1847) added a float provided with a writing style to the mercurial manometer, and brought the style to write on a drum covered with smoked paper and driven slowly round by clockwork—a kymograph. By this means tracings of the arterial blood pressure are obtained, and the influence upon the blood pressure of various agents recorded and studied. For the veins a manometer filled with salt solution is used, as mercury is too heavy a fluid to record the far slighter changes of venous pressure. The manometer may be connected with a recording tambour.

The arterial blood-pressure record obtained with the mercurial manometer exhibits cardiac and respiratory oscillations as shown in fig. 18. The method gives us a fairly accurate record of the mean pressure, but the mass of the mercury causes such inertia that the instrument is quite unable to faithfully record the systolic and diastolic variations of pressure. To effect this record, delicate spring manometers of rapid action and small inertia have been invented. A mercury manometer provided with maximum and minimum valves has also been employed to indicate the maximal systolic and minimal diastolic pressure. To determine the blood pressure in man, an instrument called the sphygmometer is used.



From Howell's *Text-Book of Physiology*, by permission of W. B. Saunders Co.

FIG. 27.—Diagram showing Systolic, Mean and Diastolic Pressure.

The writer's sphygmometer consists of a rubber bag covered with silk which is filled with air, and connected by a short length of tube to a manometer. This manometer consists of a graduated glass tube, open at one end. A small hole is in the side of the tube near this end. A meniscus of water is introduced up to the side hole—the zero mark on the scale—by placing the open end of the tube in water. The bag is now connected to the gauge so that the side hole is closed by the rubber tube. Covering the rubber bag with the hand and pressing it on the radial artery until the pulse (felt beyond) is obliterated, one reads the height to which the meniscus rises in the manometer, and this gives us the systolic pressure in the artery. The air above the meniscus acts as a spring, converting the instrument into a spring manometer. It is empirically graduated in mm. Hg.

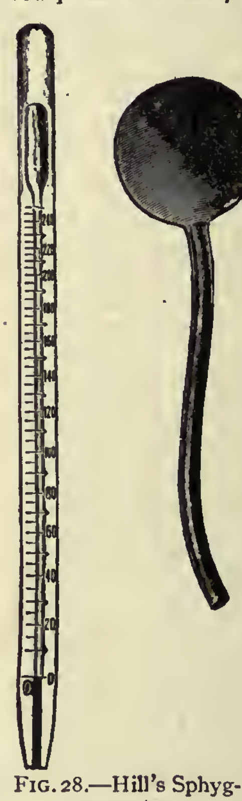


FIG. 28.—Hill's Sphygmometer.

It is very necessary to remember that the blood pressures, taken in different vessels and postures, vary with the hydrostatic pressure of the column of blood above the point of measurement. Thus in the standing posture the arterial pressure in the arteries of the leg is higher than in the arm by the height of the column of blood that separates the two points of measurement. In the horizontal posture the pressure is practically the same in all the big arteries. The pressure in the ascending aorta is kept about the same in all postures, while that of the leg arteries varies widely. The effect of gravity is compensated there by active changes in heart force, splanchnic dilatation, &c. (L. Hill). The systolic pressure of young men, taken in the radial artery with the arm at the same level as the heart, may be taken to be about 110 mm. of Hg. In men of 40–60 years the systolic pressure is often about 140 mm., but in some robust men it is no higher than in youth.

The venous pressure in man may be measured by finding the pressure just required to prevent a cutaneous vein refilling after it has been emptied beyond a valve. There is no accurate method of measuring the capillary pressure. It and the venous pressure constantly vary from nothing to a positive amount with rest or movement of muscles, change of posture, &c.

The arterial pressure is raised during exertion by the more forcible beat of the heart—*e.g.* pressures of 140–190 mm. Hg have been observed immediately after a 3-mile race. It rapidly sinks to a lower level than usual after the exertion is over, *e.g.* 90 mm. Hg, owing to the quieter action of the heart and the persistence of the cutaneous dilatation of the blood vessels which is evoked by the rise of body temperature. The writer has observed in athletes rectal temperatures of 102–105° F. after long races. After meals there is an increase in cardiac force to maintain the flow through the dilated splanchnic vessels. Mental excitement raises the pressure—*e.g.* the writer's pressure may be 110 mm. before and 125 mm. Hg after giving a lecture. The origin of the blood pressure in the arteries is the energy of the heart. The pressure gradient depends on the peripheral resistance. In the arterials the pressure is spent, and little of it reaches the capillaries. The return of the capillary blood to the veins and the pressure in the veins is due partly to the remainder of the cardiac force, but more largely to the contraction of the skeletal muscles and the viscera, to the action of gravity in changes of posture and to the respiratory pump.

The pulmonary circulation.

The pulmonary artery, carrying venous blood, divides and subdivides, and the smallest branches end in a plexus of capillaries on the walls of the air-cells of the lung. From this plexus the blood is drained by the radicles of the four pulmonary veins which open into the left auricle. The pressure in the pulmonary artery is less than one-third the aortic pressure, and the blood takes only one-third of the time to complete the pulmonary circuit that it takes to make the systemic. The four chief factors which influence the pulmonary circulation are: (1) the force and output of the right ventricle; (2) the diastolic filling action of the left auricle and ventricle; (3) the diameter of the pulmonary capillaries, which varies with the respiratory expansion of the lungs; (4) the intrathoracic pressure.

In inspiration the lungs are distended in consequence of the greater positive pressure on the inner surfaces being greater than the negative pressure on their outer pleural surfaces. The negative pressure in the intrathoracic cavity results from the enlargement of the thorax by the inspiratory muscles. When the elastic lungs are distended by a full inspiration they exert an elastic traction amounting to about 15 mm. Hg. The heart and vessels within the thorax are submitted to this traction—that is, to the pressure of the atmosphere minus 15 mm. Hg—while the vascular system of the rest of the body bears the full atmospheric pressure. The thin-walled auricles and veins yield more to this elastic traction than the thick-walled ventricles and arteries. Thus inspiration exerts a suction action, which furthers the filling of the veins and auricles. This action is assisted by the positive pressure exerted by the descending diaphragm on the contents of the abdomen. Blood is thus both pushed and sucked into the heart in increased amount during inspiration.

Experiment has shown that the blood vessels of the lungs when distended are wider than those of collapsed lungs. Suppose an elastic bag having minute tubes in its walls be dilated by blowing into it, the lumina of the tubes will be lessened, and the same occurs in the lungs if they are artificially inflated with air; but if the bag be placed in a glass bottle, and the pressure on its outer surface be diminished by removing air from the space between the bag and the side of the bottle, the bag will distend and the lumina of the tubes be increased. Thus it is evident that inspiration, by increasing the calibre of the pulmonary vessels, draws blood into the lungs, and the movements of the lungs become an effective force in carrying on the pulmonary circulation. It has been estimated that there is about one-twelfth of the whole blood quantum in the lungs during inspiration, and one-fifteenth during expiration. The great degree of distensibility of the pulmonary vessels allows of frequent adjustments being made, so that within wide limits as much blood in a given time will pass through the pulmonary as through the systemic system. The limits of their adjustment may, however, be exceeded during violent muscular exertion. The compressive action of the skeletal muscles returns the blood to the venous cistern, and if more arrives than can be transmitted through the lungs in a given time, the right heart becomes engorged, breathlessness occurs, and signs of venous congestion appear in the flushed face and turgid veins. The weaker the musculature of the heart the more likely is this to occur; hence the breathlessness on exertion which characterizes cardiac affections. The training of an athlete consists largely in developing and adjusting his heart to meet this strain. Similarly the weak heart may be trained and improved by carefully adjusted exercise. Rhythmic compression of the thorax is the proper method of resuscitation from suffocation, for this not only aerates the lungs, but produces a circulation of blood. By compressing the abdomen to fill the heart, and then compressing the thorax to empty it, the valves meanwhile directing the flow, a pressure of blood can be maintained in the aorta even when the heart has ceased to beat, and this if patiently continued may lead to renewal of the heart-beat. There is no certain evidence that the pulmonary arteries are controlled by vaso-motor nerves. In the intact animal it is difficult to determine whether a rise of pressure in the pulmonary artery is induced really by constriction of the pulmonary system, or by changes in the output of the heart; hence different observers have reached conflicting conclusions. In the case of lungs which have been supplied with an artificial circulation and a constant head of pressure to eliminate the action of the heart, no diminution in outflow has been observed in exciting the branches of the vagus or sympathetic nerves which supply the lungs, or by the injection of adrenalin (Sir Benjamin C. Brodie (1783–1862), and Dixon, Burton-Spitz).

The portal circulation.

The portal circulation is peculiar in that the blood passes through two sets of capillaries. Arterial blood is conveyed to the capillary networks of the stomach, spleen, pancreas and intestines by branches of the abdominal aorta. The portal vein is formed by the confluence of the mesenteric veins with the splenic vein, which together drain these capillaries. The portal blood breaks up into a second plexus of capillaries within the substance of the liver. The hepatic veins carry the blood from this plexus into the inferior vena cava. Ligation of the portal vein causes intense congestion of the abdominal vessels, and so distensile are these that they can hold nearly all the blood in the body: thus the arterial pressure quickly falls, and the animal dies just as if it had been bled to death. The portal circulation is largely maintained by the action of the respiratory pump, the peristaltic movements of the intestine and the rhythmic contractions of the spleen; these agencies help to drive the blood through the second set of capillaries in the liver. The systole of the heart may tell back on the liver and cause it to swell, for there are no valves between it and the inferior vena cava. Obstruction in the right heart or pulmonary circulation at once tells back on the liver. The increased respiration which results from muscular exercise greatly furthers the hepatic circulation, while it increases the consumption of food material. Thus exercise relieves the over-fed man. The liver is so vascular and extensile that it may hold one-quarter of the blood in the body.

The cerebral circulation.

The circulation of the brain is somewhat peculiar, since this organ is enclosed in a rigid bony covering. The limbs, glands and viscera can expand considerably when the blood pressure rises, but the expansion of the brain is confined. By the expression of venous blood from the veins and sinuses the brain can receive a larger supply of arterial blood at each pulse. Increase in arterial pressure increases the velocity of flow through the brain, the whole cerebral vascular system behaving like a system of rigid tubes when the limits of expansion have been reached. For as the pressure transmitted directly through the arteries to the capillary veins must always be greater than that transmitted through the elastic wall of the arteries to the brain tissue, the expansion of the arteries cannot obliterate the lumina of the veins. The pressure of the brain against the skull wall is circulatory in origin: in the infant's fontanelle the brain can be felt to pulse with each heart-beat and to expand with expiration. The expiratory impediment to the venous flow produces this expansion. A blood clot on the brain or depressed piece of bone raise the brain pressure by obliterating the capillaries in the compressed area and raising the pressure therein to the arterial pressure. The arterial supply to the brain by the two carotid and two vertebral arteries is so abundant, and so assured by the anastomosis of these vessels in the circle of Willis, that at least two of the arteries in the monkey can be tied without grave effect. Sudden compression of both carotids may render a man unconscious, but will not destroy life, for the centres of respiration, &c., are supplied by the vertebral arteries. The vertebral arteries in their passage to the brain are protected from compression by the cervical vertebrae.

Whether the muscular coat of the cerebral arteries is supplied with vaso-motor nerves is uncertain. Hürthle and others observed a rise of pressure in the peripheral end of the carotid artery on stimulating the cervical sympathetic nerve. The writer found this to be so only when the cervical sympathetic nerve was excited on the same side as the carotid pressure was recorded. If the circle of Willis was constricted, excitation of either nerve ought to have the effect; it is possible that the effect was produced by the vaso-constriction of the extra-cranial branches of the carotid. After establishing an artificial circulation of the brain Wiggins found that adding adrenalin to the nutritive fluid reduced the outflow, and it is supposed that adrenalin acts by stimulating the ends of the vaso-motor nerves, rather than by stimulating the muscular coats of the arteries. The veins of the pia and dura mater have no middle muscular coat and no valves. The venous blood emerges from the skull in man mainly through the opening of the lateral sinuses into the internal jugular vein; there are communications between the cavernous sinuses and the ophthalmic veins of the facial system, and with the venous plexuses of the spinal cord. The points of emergence of the veins are well protected from closure by compression. The brain can regulate its own blood supply by means of the cardiac and vaso-motor centres. Deficient supply to these centres excites increased frequency of the heart and constriction of the arteries, especially those of the great splanchnic area. Cerebral excitement has the same effect, so that the active brain is assured of a greater blood supply (Bayliss and L. Hill).

In each unit of time the same quantity of blood must, on the average, flow through the lesser and greater circuit, for otherwise the circulation would not continue. Likewise, the average velocity at any part of the vascular system must be inversely proportional to the total cross-section at that part. In other words, where the bed is wider, the stream is slower; the total sectional area of the capillaries is roughly estimated to be 700 times greater than that of the aorta or venae cavae. Any general change in velocity at any section of this circuit tells both backwards and forwards on the velocity in all other sections, for the average velocity in the arteries, veins and capillaries, these vessels being taken respectively as a whole, depends always on the relative areas of their total cross-sections.

The circulation during muscular activity.

The vascular system is especially constructed so that considerable changes of pressure may be brought about in the arterial section, without any (or scarcely any) alteration of the pressures in the venous or pulmonary sections of the circulatory system. A high-pressure main (the arteries) runs to all the organs, and this is supplied with taps; for by means of the vaso-motor nerves which control the diameter of the arterioles, the stream can be turned on here or there, and any part flushed with the blood, while the supply to the remaining parts is kept under control. Normally, the sum of the resistances which at any moment opposes the outflow through the capillaries is maintained at the same value, for the vascular system is so co-ordinated by the nervous system that dilatation of the arterioles in any one organ is compensated for by constriction in another. Thus the arterial pressure remains constant, except at times of great activity. The great splanchnic area of arterioles acts as "the resistance box" of the arterial system. By the constriction of these arterioles during mental or muscular activity the blood current is switched off the abdominal organs on to the brain and muscles, while by dilating during rest and digestion they produce the contrary effect. The constriction of the splanchnic vessels does not sensibly diminish the capacity of the total vascular system, for the veins possess little elasticity. Thus variations of arterial pressure, brought about by constriction or dilatation of the arterial system, produce little or no effect on the pressure in the great veins or pulmonary circuit. The contraction of the abdominal muscles, on the other hand, greatly influences the diastolic or filling pressure of the heart. It is obviously of the utmost importance that the heart should not be over-dilated by an increased filling pressure during the period of diastole.

When a man strains to lift a heavy weight he closes the glottis, and by contracting the muscles which are attached to the thorax raises the intrathoracic pressure. The rise of intrathoracic pressure aids the pericardium in supporting the heart, and prevents over-dilatation by resisting the increase in venous blood pressure. This increase results from the powerful and sustained contraction of the abdominal and other skeletal muscles. In the diagram already given it is clear that the contraction of T will counteract the contraction of A. At the same time the rise of intrathoracic pressure supports the lungs, and prevents the blood, driven out from the veins, from congesting within the pulmonary vessels. Over-dilatation both of the heart and lungs being thus prevented, the blood expressed from the abdomen is driven through the lungs into the left ventricle, and so into the arteries. So long as the general and intense muscular spasms continue, there is increased resistance to the outflow of the blood through the capillaries both of the abdominal viscera and the limbs. The arterial pressure rises, therefore, and the flow of blood to the central nervous system is increased. The rise of the intrathoracic and intra-abdominal pressures, and the sustained contraction of the skeletal muscles, alike hinder the return of venous blood from the capillaries to the heart, and, owing to this, the face and limbs become congested until the veins stand out as knotted cords. It is obvious that at this stage the total capacity of the vascular system is greatly diminished, and the pressure in all parts of the system is raised. It is during such a muscular effort that a degenerated vessel in the brain is prone to rupture and occasion apoplexy. The venous obstruction quickly leads to diminished diastolic filling of the heart, and to such a decreased velocity of blood flow that the effort is terminated by the lack of oxygen in the brain. During any violent exercise, such as running, the skeletal muscles alternately contract and expand, and the full flood of the circulation flows through the locomotor organs. The stroke of the heart is then both more energetic and more frequent, and the blood circulates with increased velocity. Under these conditions the filling of the heart is maintained by the pumping action of the skeletal and respiratory muscles. The abdominal wall is tonically contracted, and the reserve of blood is driven from the splanchnic vessels to fill the dilated vessels of the locomotor organs. The thorax is tonically elevated and the thoracic cavity enlarged, so that the pulmonary vessels are dilated. At each respiration the pressure within the thoracic cavity becomes less than that of the atmosphere, and the blood is aspirated from the veins into the right side of the heart and lungs; conversely, at each expiration the thoracic pressure increases, and the blood is expressed from the lungs into the left side of the heart. While the respiratory pump at all times renders important aid to the circulation of the blood, its action becomes of supreme importance during such an exercise as running. The runner pants for breath, and this not only increases the intake of oxygen, but maintains the diastolic filling of the heart. It is of the utmost importance that man should grasp the fact that the circulation of the blood depends not only on the heart, but on the vigour of the respiration and the activity of the skeletal muscles. Muscular exercise is for this reason a *sine quâ non* for the maintenance of vigorous mental and bodily health. Under the influence of the muscular system comes not only the blood but the lymph. The lymphatics form a subsidiary system of small valved vessels, and drain the tissues of the excess of lymph, which transudes from the capillaries of the organs during functional activity, or in consequence of venous obstruction. The larger lymphatics open into the veins at the root of the neck. It is chiefly by the compressive action of the skeletal and visceral muscles, and the aspirating action of the respiratory pump, that the lymph is propelled onwards. It must be borne in mind that the descent of the diaphragm during inspiration compresses the abdominal organs, and thus aids the aspirating action of the thorax in furthering the return to the heart both of venous blood and of lymph.

Influence of posture on the circulation.

The circulation remains efficient not only in the horizontal but also in the erect position, and just as much so when a man, like a gymnast, is ceaselessly shifting the position of his body. Yet in a man standing six feet the hydrostatic pressure of a column of blood reaching from the vertex to the soles of the feet is equal to 14 cm. of mercury. The blood, owing to its weight, continually presses downwards, and under the influence of gravity would sink if the veins and capillaries of the lower parts were sufficiently extensile to contain it. Such is actually the case in the snake or eel, for the heart empties so soon as one of these animals is immobilized in the vertical posture. This does not occur in an eel or snake immersed in water, for the hydrostatic pressure of the column of water outside balances that of the blood within. During the evolution of man there have been developed special mechanisms by which the determination of the blood to the lower parts is prevented, and the assumption of the erect posture rendered possible. The pericardium is suspended above by the deep cervical fascia, while below it is attached to the central tendon of the diaphragm. Almost all displacement of the heart is thus prevented. The pericardium supports the right heart when the weight of a long column of venous blood suddenly bears upon it, as, for example, when a man stands on his head. The abdominal viscera are slung upwards to the spine, while below they are supported by the pelvic basin and the wall of the abdomen, the muscles of which are arranged so as to act as a natural waist-band. In tame hutch rabbits, with large patulous abdomens, death may result in from 15 to 30 minutes if the animals are suspended and immobilized in the erect posture, for the circulation through the brain ceases and the heart soon becomes emptied of blood. If, however, the capacious veins of the abdomen be confined by an abdominal bandage, no such result occurs. Man is naturally provided with an efficient abdominal belt, although this in many is rendered toneless by neglect of exercise and gross or indolent living. The splanchnic arterioles are maintained in tonic contraction by the vaso-motor centre, and thus the flow of blood to the abdominal viscera is confined within due limits. The veins of the limbs are broken into short segments by valves, and these support the weight of the blood in the erect posture. The brain is confined within the rigid wall of the skull, and by this wall are the cerebral vessels supported and confined when the pressure is increased by the head-down posture. Every contraction of the skeletal muscles compresses the veins of the body and limbs, for these are confined beneath the taut and elastic skin. The pressure of the body against external objects has a like result. Guided by the valves of the veins, the blood is by such means continually driven upwards into the venae cavae. If the reader hangs one arm motionless, until the veins at the back of the hand become congested, and then either elevates the limb or forcibly clenches the fist, he will recognize the enormous influence which muscular exercise, and continual change of posture, has on the return of blood to the heart. It becomes wearisome and soon impossible for a man to stand motionless. When a man is crucified—that is to say, immobilized in the erect posture—the blood slowly sinks to the most dependent parts, oedema and thirst result, and finally death from cerebral anaemia ensues. In man, standing erect, the heart is situated above its chief reservoir—the abdominal veins. The blood is raised by the action of the respiratory movements, which act both as a suction and as a force pump, for the blood is not only aspirated into the right ventricle by the expansion of the thoracic cavity, but is expressed from the abdomen by the descent of the diaphragm. When a man faints from fear, his muscular system is relaxed and respiration inhibited. The blood in consequence sinks into the abdomen, the face blanches and the heart fails to fill. He is resuscitated either by compression of the abdomen, or by being placed in the head-down posture. To prevent faintness and drive the blood-stream to his brain and muscles, a soldier tightens his belt before entering into action. Similarly, men and women with lax abdominal wall and toneless muscles take refuge in the wearing of abdominal belts, and find comfort in prolonged immersion in baths. It would be more rational if they practised rope-hauling, and, like fishermen, hardened their abdominal muscles.

In the mature foetus the fluid brought from the placenta by the umbilical vein is partly conveyed at once to the vena cava ascendens by means of the *ductus venosus* and partly flows through two trunks that unite with the portal vein, returning the blood from the intestines into the substance of the liver, thence to be carried back to the vena cava by the hepatic vein. Having thus been transmitted through the placenta and the liver, the blood that enters the vena cava is purely arterial in character; but, being mixed in the vessels with the venous blood returned from the trunk and lower extremities, it loses this character in some degree by the time that it reaches the heart. In the right auricle, which it then enters, it would also be mixed with the venous blood brought down from the head and upper extremities by the descending vena cava were it not that a provision exists to impede (if it does not entirely prevent) any further admixture. This consists in the arrangement of the Eustachian valve, which directs the arterial current (that flows upwards through the ascending vena cava) into the left side of the heart, through the foramen ovale—an opening in the septum between the auricles—whilst it directs the venous current (that is being returned by the superior vena cava) into the right ventricle. When the ventricles contract, the arterial blood contained in the left is propelled into the ascending aorta, and supplies the branches that proceed to the head and upper extremities before it undergoes any further admixture, whilst the venous blood contained in the right ventricle is forced into the pulmonary artery, and thence through the *ductus arteriosus*—branching off from the pulmonary artery before it passes to the two lungs—into the descending aorta, mingling with the arterial currents which that vessel previously conveyed, and thus supplying the trunk and lower extremities with a mixed fluid. A portion of this is conveyed by the umbilical arteries to the placenta, in which it undergoes the renovating influence of the maternal blood, and from which it is returned in a state of purity. In consequence of this arrangement the head and upper extremities are supplied with pure blood returning from the placenta, whilst the rest of the body receives blood which is partly venous. This is probably the explanation of the fact that the head and upper extremities are most developed, and from their weight occupy the inferior position in the uterus. At birth the course of the circulation undergoes changes. As soon as the lungs are distended by the first inspiration, a portion of the blood of the pulmonary artery is diverted into them and undergoes aeration; and, as this portion increases with the full activity of the lungs, the ductus arteriosus gradually shrinks, and its cavity finally becomes obliterated. At the same time the foramen ovale is closed by a valvular fold, and thus the direct communication between the two auricles is cut off. When these changes have been accomplished, the circulation, which was before carried on upon the plan of that of the higher reptiles, becomes that of the complete warm-blooded animal, all the blood which has been returned in a venous state to the right side of the heart being transmitted through the lungs before it can reach the left side or be propelled from its arterial trunks. After birth the umbilical arteries shrink and close up and become the lateral ligaments of the bladder, while their upper parts remain as the superior vesical arteries. The umbilical vein becomes the ligamentum teres. The ductus venosus also shrinks and finally is closed. The foramen ovale is also closed, and the ductus arteriosus shrivels and becomes the ligamentum arteriosum.

Foetal.

The blood vessels are supplied with constrictor and dilator nerve fibres which regulate the size of the vascular bed and the distribution of the blood to the various organs. The arteries may be compared to a high pressure main supplying a town. By means of the vaso-motor nerves the arterioles (the house taps) can be opened or closed and the current switched on to or off any organ according to its functional needs. If all the arterioles be dilated at one and the same time, the aortic pressure falls, and the blood taking the pathways of least resistance, gravitates to the most dependent parts of the vascular system, just as if all the taps in a town were opened at once the pressure in the main would fail, and only the taps in the lower parts of the town would receive a supply. The discovery of the vaso-motor nerves is due to Claude Bernard (1851). He discovered that by section of the cervical sympathetic nerve he could make the ear of a rabbit flush, while by stimulation of this nerve he could make it blanch. Claude Bernard had the good fortune to make the further discovery that stimulation of certain nerves, such as the chorda tympani supplying the salivary gland, produces an active dilatation of the blood vessels. The vaso-constrictor fibres issue in the anterior spinal roots, from the second thoracic to the second lumbar root, and pass to the sympathetic chain of ganglia. The fibres are of small diameter, and probably arise from cells situated in the lateral horn of the grey matter of the spinal cord. They each have a cell station in one other ganglion and proceed as post-ganglionic fibres to the cervical sympathetic, to the mesenteric nerves and to the nerves of the limbs. Nicotine paralyses ganglion cells, and by applying this test to the various ganglia the cell stations of the vaso-constrictor fibres supplying each organ have been mapped out. The vaso-dilator fibres have not so restricted an origin, for they issue in the efferent roots in all parts of the neural axis. The two kinds of nerves, although antagonistic in action, end in the same terminal plexus which surrounds the vessels. The presence of vaso-dilator fibres in the common nerve trunks is masked, on excitation, by the overpowering action of the vaso-constrictor nerves. The latter are, however, more rapidly fatigued than the former, and by this and other means the presence of vaso-dilator fibres can be demonstrated in almost all parts of the body. The nervi-erigentes to the penis and the chorda tympani supplying the salivary glands are the most striking examples of vaso-dilator nerves. The vaso-dilator nerves for the limbs issue in the posterior spinal roots (Bayliss). The posterior roots contain the afferent nerves (touch, pain, &c.). Excitation of these fibres causes reflexly a rise of blood pressure directly, a vaso-dilatation of the part the nerves supply. Thus it is assured that the irritated or injured part receives immediately a greater supply of blood. The vaso-motor centre exerts a tonic influence over the calibre of the arterial and portal systems.

The vaso-motor nerves.

Much labour has been done since to determine the origin and exact distribution of the vaso-motor nerves to the various organs, and the reflex conditions under which they come normally into action, and, as the fruit, our knowledge of these inquiries has come to a condition of considerable exactness. This knowledge is of great practical importance to the physician, and it is worth noting that it has been obtained entirely by experiment on living but anaesthetized animals. No dissections of the dead animal could have informed us of the vaso-motor nerves. Vaso-motor effects can be studied by (1) inspection of the flushing or blanching of an organ; (2) measuring the venous outflow; (3) recording the pressure in the artery going to and the vein leaving the organ; (4) observations on the volume of an organ. To make these observations, the organ is enclosed in a suitable air-tight box or plethysmograph, an opening being contrived for the vessels of the organ to pass through so that the circulation may continue. The box is filled with air or water and is connected with a recording tambour (see fig. 18).

The chief effects of vaso-constriction are an increased resistance and lessened flow through the organ, diminished volume and tension of the organ, the venous blood issues from it darker in colour and the pressure rises in the artery and falls in the vein of the organ, and its temperature sinks. Lastly, if a large area be constricted the general arterial pressure rises.

The centre is situated in the spinal bulb beneath the middle of the floor of the fourth ventricle. The tone of the vascular system is not disturbed when the great brain and mid brain is destroyed as far as the region of the pons Varolii, but as soon as the spinal bulb is injured or destroyed the arterial pressure falls very greatly, and the animal passes into the condition of surgical shock if kept alive by artificial respiration. Painting the floor of the fourth ventricle with a local anaesthetic, *e.g.* cocaine, has the same lowering effect on the blood pressure. Division of the cervical spinal cord or of the splanchnic nerves lowers the blood pressure greatly. The one lesion cuts off the whole body, the other the abdominal organs from the tonic influence of the centre. The fall of pressure is due almost entirely to the pooling of the blood in the portal veins and vena cava inferior. On the other hand, electrical excitation of the lower end of the divided cord or splanchnic nerves raises the pressure by restoring the vascular tone. If an animal be kept alive after division of the spinal cord in the lower cervical region, as it may be, for the phrenics, the chief motor nerves of respiration, come off above this region, it is found that the vascular tone after a time becomes restored and the condition of shock passes away. By no second section of the spinal cord can the general condition of shock be reproduced, but a total obstruction of the cord once more causes a general loss of the vascular tone. From the experimental result, so obtained, it is argued that subsidiary vaso-motor centres exist in the spinal cord, and there is evidence to show that these centres may be excited reflexly. After the lumbar cord has been destroyed the tone of the vessels of the lower limbs is recovered in the course of a few days. In this case the recovery is attributed to the ganglionic and nervous structures which are intercalated between the spinal cord and the muscular walls of the blood vessels. There are thus three mechanisms of control, the bulbar centre influenced particularly by the visual, auditory and vestibular nerves, the spinal centres and the peripheral ganglionic structures.

The vaso-motor centre is reflexly excited by the afferent nerves, and its ever-varying tonic action is made up of the balance of the "pressor" and "depressor" influences which thus reach it, and from the quality of the blood which circulates through it. Pressor effects, *i.e.* those causing increased constriction and rise of arterial pressure, may be produced by stimulating the central end of almost any afferent nerve, and especially that of a cutaneous nerve. Depressor effects are always obtained by stimulating the depressor nerve, and may be obtained by stimulating the afferent nerves under special conditions. That these reflex vaso-motor effects frequently occur is shown by the blush of shame, the blanching of the face by fear, the blanching of the skin by exposure to cold and the flushing which is produced by heat. The rabbit's ear blanches if its feet are put into cold water. The vaso-motor mechanism is one of the most important of those mechanisms which control the body heat. Stimulation of the nasal mucous membrane causes flushing of the vessels of the head, constriction elsewhere and a rise of arterial pressure. Food in the mouth, or even the sight or smell of food, cause dilatation of the vessels of the salivary gland. The mucous membrane of the air passages flush and secrete more actively when a draught of cold air strikes the skin. Ice placed on the abdomen constricts not only the vessels in the skin but those in the kidney. Many other examples might be given of the control which the vaso-motor system exerts, but the above are sufficient to suggest the influence which the physician can bring to bear on the blood supply of the various organs.

Discussion has taken place as to whether depressor reflexes are brought about by lessening of the vaso-constrictor tone or by excitation of vaso-dilator nerves. Proof of an undoubtable character seems to have been produced that after division of the vaso-constrictor nerves dilatation of a limb can be brought about reflexly by stimulating the depressor nerve, and in this case the effect must be produced by active excitation of the vaso-dilator nerves.

Under certain unusual conditions, *e.g.* deficient supply of oxygen, the vaso-motor centre exhibits rhythmical variations in tonicity which make themselves visible as rhythmical rises and falls of arterial pressure of slow tempo. A waxing and waning of respiration (Cheyne-Stokes breathing) frequently accompanies these waves. Such are observed in sleep, especially in children and in hibernating animals.

Bibliography.—References to all the authoritative papers up to 1892 on the circulation of the blood will be found in Tigerstedt's *Lehrbuch der Physiologie des Kreislaufs*, and up to 1905–1908 in the articles on the circulation published in Nagel's *Handbuch der Physiologie des Menschen*, viz. "Allgemeine Physiologie des Herzens, Die Innervation der Kreislaufsorgane," by F. B. Hofmann, "Die Mechanik der Kreislaufsorgane," by O. Frank. An elementary introduction to the subject will be found in Leonard Hill's *Manual of Physiology*, and a more extensive treatment of it in the same author's article on the "Mechanism of the Circulation," and Gaskell's article on the "Heart" in Schäfer's *Text-Book of Physiology*, or in one of the larger text-books of physiology, such as that of Howell, Stewart Halliburton or Starling. (L. E. H.)

IV. Pathology of the Vascular System

On account of its intimate relations with every part of the body, the circulation is prone to disturbances arising from a great series of causes. Some of these produce effects which may be regarded as functional—mere changes in metabolism, whose disturbances react upon the rest of the body; others give rise to definite structural alterations. In considering the pathology of the circulation, it is useful to divide it into that of the heart, that of the blood vessels and that of the blood.

The heart. The heart is liable to changes in the pericardium, malformations, changes in the myocardium, changes in the endocardium, valvular lesions and functional disorders.

(1) *The pericardium* may become the seat of morbid changes in various cardiac enlargements, it may become stretched or distended; but the most common and important of the changes is an inflammatory one, *i.e. pericarditis.* This may arise by way of the blood stream, as in rheumatism, scarlatina and other infective diseases, or by way of the lymph stream. The micro-organisms chiefly responsible for the production of pericarditis are the pneumococcus, the different varieties of streptococci and staphylococci, the bacillus tuberculosis, the bacillus coli, and sometimes the gonococcus. In the acute form of the disease the shining serous membrane becomes first dull and lustreless, the blood vessels engorged and an exudation of serum takes place; then fibrin is deposited both on the visceral and parietal layers. When the fluid is insufficient to keep the surfaces apart, the separation at each diastole gives rise to the well-known "friction rub." Sometimes the amount of exudation pent up in the pericardial sac is so great as to necessitate its being drawn off. The fluid may be serous or sero-fibrinous, or may be haemorrhagic, or have undergone a putrefactive change. An effusion of serous fluid into the pericardial sac causes considerable embarrassment to the course of the blood, by rendering the negative pressure, normally present in the sac, positive. The reason for the interference with the circulation brought about by this alteration of pressure is that the auricles are by compression rendered incapable of accommodating the blood-return from the veins. Analogous effects are produced by pressure upon the heart from without, whether by aneurysm or tumour, and pleural effusion or pneumothorax, affecting the viscera from without. In pericarditis it has further to be remembered that the effect of the process itself upon the muscle fibres lying beneath the membrane is to cause a softening of texture and weakening of function, whereby the driving power of the heart is diminished. In obliteration of the pericardium, again, the presence of the adhesions between these two layers leads to interference with the contraction of the myocardium, whereby its functions are interfered with. Acute ventricular dilatation may be associated with pericarditis particularly when the latter is of rheumatic origin and is the result of the myocardial softening referred to. Pericardial effusions usually undergo absorption, but various adhesions, and thickenings known as "white spots," may remain. Effusions other than inflammatory are found in the pericardium, *i.e. hydropericardium*, a dropsical accumulation, may be mistaken for an inflammatory one. It occurs in scarlatina, Bright's disease, as part of a general dropsy, or occasionally from some mechanical difficulty interfering with the local circulation. When the fluid is abundant, it may produce the effects noticed under the inflammatory effusion, and the pericardium may become soddened and its endothelium degenerated. *Haemopericardium*, or blood in the pericardium, may occur apart from the amount that may be mixed with inflammatory effusions. It is associated with foreign bodies penetrating from the oesophagus, rupture of an aneurysm, or occasionally associated with scurvy and purpura. Gas and air may sometimes distend the pericardium. It is also liable to new growths, which are usually secondary in character, and tuberculosis and hydatids are sometimes found.

(2) *Malformations.*—We are ignorant of the causes which lead to imperfect development of the heart. Many of its malformations are of purely pathological interest, but others, such as deficiencies of the intraventricular septum, non-closure of the foramen ovale, patency of the ductus arteriosus, or malformations of the valves, produce a series of secondary effects resultant on the deficient aeration of the blood and sluggishness of the circulation and of venous congestion. The train of symptoms is similar to those mentioned below under acquired valvular lesions, but dropsy is very rare.

(3) *The Myocardium.*—The coverings of the heart muscle cannot long be diseased without affecting the contractile substance itself. Any morbid changes in the lung tissues which impede the circulation through them, and more particularly emphysema, lead to change in the substance of the right ventricle, while morbid changes in the systemic arteries lead to changes in the left ventricle. In *hypertrophy* we have an increase of substance. Tangl found by direct measurement that the muscle cells are increased in diameter. The hypertrophy may be due to increased work thrown upon the muscle, as in athletics (idiopathic hypertrophy), or may be compensatory, when the muscle is trying to overcome a circulatory defect, as in valvular stenosis or regurgitation. Hypertrophy, when within physiological limits, is to be considered as a means of adaptation. When occurring in pathological circumstances, it must be regarded as a method of compensation. Every structure and every function in a healthy body has greater or lesser reserve of energy. In healthy conditions the ordinary demands made upon various organs are far below their possible responses, and if these be excessive in extent or duration, the organs adapt themselves to the conditions imposed on them. In abnormal circumstances the process of hypertrophy is brought about by the power which the structures have of responding to the demands made upon them; and so long as the process is adequate, all disturbances may be averted. As an example of such readjustment may be cited the fact that in chronic renal cirrhosis, with increased thickness of the middle tunic of the arteries, there is hypertrophy of the left ventricle.

Dilatation of the heart is due to the inability of the heart muscle to expel the contents of its cavities. It may occur from temporary overstress or in the failing compensation of valvular disease, or may accompany pathological changes in the muscle such as myocarditis or one of the degenerations.

From the presence of toxic substances in the blood (whether introduced from without or arising within the body) the cells of the cardiac muscle fibres are apt to undergo what is termed *cloudy swelling*—the simplest form of degenerative process. The cells become larger and duller, with a granular appearance, and the nuclei are less distinct. As a result of interference with nutrition, whether by simple diminution or perverted processes, *fatty degeneration* ensues. It may be associated, but is not necessarily connected, with adipose accumulation and encroachment commonly termed infiltration. In true fatty degeneration the muscle cells have part of their protoplasm converted into adipose tissue. The fibres become granular, and the cells lose their definition, while the nuclei are obscure.

The myocardium undergoes both acute and chronic reaction changes. In the former there is enlargement of the nuclei, with proliferation but without karyokinesis. The muscle cells become swollen and lose their striation, while they are softer in texture and altered in outline. The intermuscular tissues are swollen, and may be invaded by leucocytes; this may end in abscess formation or in the production of newly formed fibrous tissue. Chronic processes affecting the myocardium give rise to a large amount of fibrosis, and the newly formed fibrous tissue separates and compresses the areas of muscle fibres, giving rise to what is commonly known as chronic interstitial myocarditis.

Restitution or recovery may occur to a varying extent in almost all of the disease-processes which have been considered, but it has to be kept in view that in certain of the degenerative affections there is little if any possibility of getting rid of the results of the process, which in the reactive changes terminating in the formation of much fibrous tissue, or its conversion into adipose or calcareous material, the same holds true. Many of the changes, which are no doubt in their essence conservative, lead to far-reaching consequences, by their interference with nutritive possibilities.

Diseased conditions of the myocardium are frequently associated with atheromatous degenerations of the coronary arteries, and angina pectoris is said to depend upon such state of malnutrition.

The causes which operate by means of the myocardium are almost invariably of a secondary character. The various degenerations already detailed, and the different forms of myocarditis, as well as simple debility of the muscle, are all examples of changes due to general or local disturbance. All processes which directly or indirectly interfere with the energy of the walls of the heart produce twofold effects, by diminishing the aspiratory or suction-pump action during diastole, and by lessening its expulsive or force-pump action during systole. The immediate result upon the heart itself of such disturbances is dilatation of that cavity immediately affected. This may occur under perfectly healthy conditions. In these, however, the dilatation is evanescent, while in the circumstances now under consideration it is permanent, and, although compensated, it leads to persistent dilatation. Upon the blood vessels the result, whether on account of diminished aspiratory or propulsive energy, is that the amount of blood in the arterial system is decreased, while it is increased in the venous. It is not a necessary consequence that because there is less blood in the arteries the arterial pressure will be diminished, or the venous pressure increased because the veins contain more than their normal amount of blood, seeing that the blood pressure depends upon many different factors. It is a fact, nevertheless, that in consequence of the alteration in the relative amount of blood in the arteries and veins there is a considerable disturbance of blood pressure. Gravitation may overcome the contractile and elastic factors, and several consequences arise from the resulting venous engorgement. From transudation, oedema of the dependent parts of the body and the serous membranes occurs. From the sluggish nature of the current, the blood absorbs too much carbonic acid and loses too much oxygen, hence cyanosis is the result. On account, also, of the slowness of the circulation, there is a longer period for radiation of heat, and the superficial parts of the body accordingly become cold.

The engorgement of internal organs leads to distinct changes in them. The solid viscera, such as the liver, the spleen, the kidney and the lung, become enlarged and hyperaemic, and if the disturbance be continued, cyanotic atrophy ensues. Change in structure, with loss of function, takes place from blocking of the vessels by blood-clot, whether due to coagulation on the spot, or by the conveyance thither of clots formed elsewhere; a cirrhotic termination also is not infrequent, although there is still some doubt whether in this latter condition other concomitant causes have not at the same time been operative. The brain, although suffering less from hyperaemia, is subject to disturbance of the circulation through it, while it is a common seat of embolic and thrombotic processes. The heart itself, lastly, suffers in consequence of the disturbed circulation through it, and by undergoing venous stasis, with weakening of its walls and increase of its fibrous tissue, it completes the final link in a vicious circle. Effusion into the serous sacs, such as the pleura, the pericardium and the peritoneum, leads to great disturbance of the viscera with which they are connected. The mucous membranes, both respiratory and digestive, become the seat of catarrhal changes in consequence of the backward pressure and impure blood.

(4) *Changes in the Endocardium.*—In *endocarditis*, or inflammation of the lining membrane of the heart, that portion of the membrane which covers the valves is invariably affected first. Two varieties of endocarditis are described, simple and infective or ulcerative, but it is difficult to separate them pathologically. Both result from poisoning of the membrane by micro-organisms and their toxins; the main difference seems to lie in the variety of micro-organism present. Simple endocarditis may be associated with a variety of diseases, acute rheumatism and scarlet fever being the most frequent. In many fatal cases of chorea associated with endocarditis the micrococcus rheumaticus has been found in the endocardium, while the streptococci present in tonsilitis have produced endocarditis in animals. The membrane covering the valves loses its smoothness, granulations or elevations forming on the free edges; then the endothelium proliferates and is destroyed and fibrin becomes deposited, producing what is termed a "vegetation." In the lower layers of this vegetation micro-organisms can be demonstrated. Finally, portions of the vegetations may be broken off and carried as emboli in the blood stream, or two valves may become glued together, narrowing the opening and producing stenosis, or the deformed valves may be unable to close properly and regurgitation takes place. Thus the lesions of valvular disease are produced. In infective or ulcerative endocarditis, occurring in conjunction with such diseases as pyaemia, septicaemia, smallpox and pneumonia, pyogenic micrococci are carried into the blood stream, and purulent deposits take place around the valves. In this case, however, the emboli are septic, and when carried to distant tissues produce there ulceration and pus-formation. Numerous abscesses may occur in the wall of the heart muscle itself.

(5) *Valvular Lesions.*—All the valves of the heart are not equally liable to disease; those most frequently affected are the aortic and mitral valves. We have seen how the lesions of the valves are brought about. A valvular lesion may act in two ways: it may impede the onward flow of the blood by narrowing the orifice, or the mal-closure of the valves may allow a reflux of blood. Either of these processes may occur at any of the valvular orifices of the heart. Obstruction is usually complicated by some regurgitation as well, though the converse does not hold good. An increase of the quantity of blood in the auricles, particularly the left, has a less marked effect on the heart itself than an increase in the contents of the ventricles, owing to the left auricle being in continuity with the pulmonary system; whereas if the amount of blood in the left ventricle be doubled the ventricle must dilate in order to accommodate it. The reserve power of the heart is called upon to meet the dilatation, the muscular tissues becoming hypertrophied, and a more powerful systole is produced. As the left is the chief ventricle to undergo this change, the apex of the heart becomes displaced downwards. Similar changes take place in the right ventricle in pulmonary stenosis or tricuspid incompetency. Changes in the right ventricle other than primary valvular disease of the right side of the heart are frequently preceded by mitral incompetence, and are due to extra pressure being thrown upon the pulmonary semilunar valves by the pressure in the overfull pulmonary system. In mitral regurgitation the accumulation of blood in the right auricular cavity leads to its dilatation and an engorgement of the pulmonary vessels, pulmonary oedema and induration of the lung, which in turn affects the right heart. Should compensatory hypertrophy of the right ventricle fail to be established, we get the general venous congestion, dropsy and sequence before alluded to.

(6) *Functional Cardiac Disorders.*—Cardiac rhythm may be modified in several ways; there may be variation in either the length or the strength of the beat, or the beats may not be asynchronous. In palpitation or *tachycardia* its frequency is increased. This increase depends upon the inhibition of the action of the cardio-inhibitory centre, impulses passing to it from the stomach (as in dyspepsia) or from other organs. Tachycardia is also produced by toxic action, as in diphtheria and Graves's disease. In *bradycardia* the frequency is diminished. It may be due to toxins or to degenerative changes. Intermittence may simulate bradycardia, though the actual rate of the beat is not lessened; but the weak beats fail to reach the periphery. Various irregularities may take place, dependent upon perverted nerve action. It is considered that the intrinsic nerve elements play a large part in these, and in some forms of disease the irregularity is of myocardial origin.

The blood vessels.

The blood vessels possess the properties of contractility and elasticity in different degrees. Their contractility is characterized by great tonicity, considerable rhythmic action and little or no rapidity of contraction. Their elasticity stores up energy in a potential condition, and this may be liberated in kinetic form as required. The vessels are supported in various degrees by the different tissues in which they are found. In the more solid viscera they are strongly supported, as in the liver and kidney, while in those which are less dense, as in the case of the brain and the lungs, they are not so well sustained.

In many conditions the contractility and elasticity of the blood vessels become diminished according as they may be involved in various pathological processes—purulent, tuberculous or syphilitic. Chronic toxic conditions lead to numerous degenerations, such as fatty degeneration or *hyaline degeneration* of muscle fibre, apparently as the effect of coagulative processes. The tissues assume a somewhat glassy appearance, with a distinct tendency towards segmentation. *Calcareous infiltration* is brought about by the deposition of lime salts in tissues which have previously undergone fatty or fibroid changes; it particularly affects the arteries in senile affections. In consequence of many toxic agencies as part of a senile change, and as the effect of long-continued stress, the blood vessels undergo a loss of their normal properties. This is compensated by the growth of an excessive amount of fibrous tissue, leading to various forms of *arterial sclerosis*, of which the best known are *endarteritis obliterans*, which affects the smaller arteries and is due to a toxic irritant and may occur at any age, and *endarteritis deformans* (*atheroma*), which affects the larger arteries during middle age, and is usually due to mechanical irritation. As the result of these fibrous changes there is interference with the blood current, since the vessels become unyielding yet frangible, instead of distensile and elastic, tubes. The sclerotic changes lead, moreover, to dilatation of blood vessels, as well as to the formation of definite aneurysms. They also pave the way for coagulation of blood within them, *i.e.* thrombosis, while in certain situations, more particularly in the brain and in the kidney, rupture is apt to take place. Upon the heart also these changes bring about far-reaching effects. Dilatation, accompanied by hypertrophy, is a certain result of generalized arterial degeneration, while changes in the coronary arteries lead to some of the definite results in the walls of the heart which have already been considered.

Veins are subject also to mechanical and toxic effects. The pressure of abdominal tumours, the effects of the weight of a column of blood on a long vein, constipation or obstruction to the venous return may cause dilatations or varicosity. The dilatation thins the walls of the veins and the valves become incompetent; the dilated vessel then becomes twisted and the surrounding tissues thickened by the growth of fibrous tissue. The thinned walls may rupture, and, owing to the loss of the valves, extensive haemorrhages may take place. Thrombosis may follow the slowing of the blood current, and phleboliths are produced by the deposit of lime salts in it. *Phlebitis* is an acute inflammation of a vein. Apart from injury it usually follows invasion by a septic thrombus, as in the well-known *phlegmasia alba dolens*, when an infective clot from the uterine sinuses reaches the iliac veins. The pathology of the blood itself is treated under BLOOD.

VASE (through Fr. from Lat. *vas*, a vessel, pl. *vasa*, of which the singular *vasum* is rarely found; the ultimate root is probably *was-*, to cover, seen in Lat. *vestis*, clothing, Eng. "vest," Gr. ἐσθής, and also in "wear," of garments), a vessel, particularly one of ornamental form or decoration; the term is often confined to such vessels which are uncovered and with two handles, and whose height is great in proportion to their width. It is the general term applied to the decorative pottery of the ancient Greeks and Romans, of whatever shape (see CERAMICS).

VASELINE, or mineral jelly, the *Paraffinum molle* of the British Pharmacopoeia, a commercial product of petroleum which is largely employed in pharmacy, both alone and as a vehicle for the external application of medicinal agents, especially when local action rather than absorption is desired, and as a protective coating for metallic surfaces. "Vaseline" is a registered proprietary name (coined from the German *Wasser*, water, the Greek ἔλαιον, oil, and the termination *-ine*), and is strictly applicable only to the material manufactured by one company (the Chesebrough Manufacturing Company), but it is commonly applied in a generic sense. As met with in commerce, vaseline is a semi-solid mixture of hydrocarbons, having a melting-point usually ranging from a little below to a few degrees above 100° F. It is colourless, or of a pale yellow colour, translucent, fluorescent, amorphous and devoid of taste and smell. It does not oxidize on exposure to the air, and is not readily acted on by chemical reagents. It is soluble in chloroform, benzene, carbon bisulphide and oil of turpentine. It also dissolves in warm ether and in hot alcohol, but separates from the latter in flakes on cooling.

The process employed by the Chesebrough Manufacturing Company in the manufacture of vaseline is said to consist essentially in the careful distillation of selected crude petroleum, vacuum-stills being used to minimize dissociation, and filtration of the residue through granular animal charcoal. The filters are either steam-jacketed, or are placed in rooms heated to 120° F., or higher. The first runnings from the filters are colourless, and when they become coloured to a certain extent they are collected for use as a lubricant under the name of "filtered cylinder oil." (B. R.)

VASILKOV, a town of Russia, in the government of Kiev, 23 m. by rail S.W. of the city of Kiev. Pop. 18,000, chiefly agricultural. Vasilkov was founded in the 10th century, but laid waste during the Mongol invasion of 1239–42. In 1320 it was taken by the Lithuanians, and later by the Poles, under whom it remained until 1686, when it was annexed to Russia.

VASLUI, the capital of the department of Vaslui, Rumania; on a hill at the confluence of the Bêrlad and Vaslui rivers, and on the railway from Jassy to Galatz. Pop. (1900) 13,405. There are a fine old church and ruins of a palace built in 1471 by Stephen the Great. The chief trade is in corn, wine, cattle and timber. A fair is held yearly on the first ten days of September.

VASSAL (Fr. *vassal, vassaut, vassault*, &c.), the tenant and follower of a feudal lord (see FEUDALISM). The etymology of the word has been a matter of considerable dispute. The late Henri de Tourville, in his *Histoire de la formation particulariste*, maintained that vassal is derived from the German *Gast*, a guest, meaning an outsider to whom a portion of a free domain was assigned in return for rent and certain fixed services. This derivation has a somewhat fantastic air, and seems to have been framed to suit an hypothesis. The commonly accepted etymology is from the Breton *gwaz*, Welsh *gwas*, a lad or a servant. As the word in its Latin form *vassus* was at first uniformly employed in the sense of slave, this explanation is the more acceptable of the two. If it is correct we may say that "vassal" was analogous in origin to the name of "boy" given to a coloured servant by Europeans in Asia and Africa. The word gained in dignity under the Frankish empire through the *vassi dominici, i.e.* servants of the royal household, great officers of state, who were sent on extraordinary missions into the provinces, to act as assessors to the counts in the courts, or generally to settle any questions in the interests of the central power. Sometimes they were sent to organize and govern a march, sometimes they were rewarded with benefices, and as, with the growth of feudalism, these developed into hereditary fiefs, the word *vassus* or *vassallus* was naturally retained as implying the relation to the king as overlord, and was extended to the holders of all fiefs whether capital or mediate. As feudal independence increased, the word vassal lost every vestige of its original servile sense, and, since it had come to imply a purely military relation, acquired rather the meaning of "free warrior." Thus in medieval French poetry *vasselage* is commonly used in the sense of "prowess in arms," or generally of any knightly qualities. In this sense it also became acclimatized in England, and "vassal" came to be used as equivalent to free-born, soldierly, valiant and loyal, in which sense it is commonly used in medieval poetry. In countries which were not feudally organized—in Castile, for instance—vassal meant simply subject, and during the revolutionary period acquired a distinctly offensive significance as being equivalent to slave. The diminutive form *vasseletus*, for the son of a vassal, after strange fortunes returned to something of its original sense of "household servant" in the modern "valet" (*q.v.*) (see also VAVASSOR).

See *Dictionnaire de l'ancienne langue française* (Paris, 1895), for numerous examples of the use of the word vassal; also Du Cange, *Glossarium, s.* "Vassus."

VASSAR COLLEGE, a non-sectarian institution for the higher education of women, about 2 m. E. of Poughkeepsie, New York, U.S.A. It was incorporated in 1861 as Vassar Female College (which was changed to Vassar College in 1867), and was named in honour of its founder,[1] Matthew Vassar, who transferred to a board of trustees of his own selection about $400,000 (increased by his will to twice that amount) and the tract of about 200 acres of land upon which the college was built. Building began in June 1861, and the institution was opened on the 20th of September 1865, with John Howard Raymond[2] (1814–1878) as president, and Hannah W. Lyman (1816–1871) as lady principal; it had a faculty of eight professors and twenty instructors and teachers, and an enrolment of 353 pupils. The first graduating class was that of 1867, and comprised four members, to whom were given temporary certificates stating that they were "entitled to be admitted to the *First Degree of Liberal Arts*," as the propriety of awarding the degree of "bachelor" to

[1] Matthew Vassar (1791–1868) was born at East Dereham, Tuddenham parish, Norfolk, England, on the 29th of April 1791, son of a Baptist who emigrated to the United States in 1796, settled 3 m. E. of Poughkeepsie in 1797 and in 1801 established a brewery there. The brewery was burned in 1811, and Matthew took up the business and in 1812 established an "ale and oyster saloon" and a brewery, from which he became wealthy. He was a prominent member of the Baptist church. He got the idea of founding a college for women from his niece, Lydia Booth, a school teacher. He died on the 23rd of June 1868 while reading his farewell report to the Board of Trustees. His nephew, MATTHEW VASSAR, Jun. (1809–1881), was born in Poughkeepsie, became manager of his uncle's brewery, was a member of the Board of Trustees of Vassar College, and its treasurer until his death, gave in all about $500,000 to the institution, and with his brother, John Guy Vassar (1811–1888), also one of the trustees and a benefactor of the college, gave to the college the Vassar Brothers' Laboratory.

[2] Raymond graduated at Union College in 1832; studied law and then (at Hamilton, N.Y.) theology; in 1839–49 taught rhetoric and English literature at Madison (now Colgate) University, at Hamilton, N.Y.; was professor of belles-lettres at Rochester University in 1850–56; and organized the Brooklyn Polytechnic Institute in 1856–65.

women was questioned at that time; in 1868 these certificates were replaced by diplomas bestowing the degree of A.B. The present equipment includes more than twenty buildings, and the campus has an area of about 400 acres. The college confers the baccalaureate degree in arts (A.B.) upon the completion of the regular course of four years, and a second degree in arts (A.M.) upon Bachelors of Arts of Vassar or any approved college who have completed (by examination and thesis) a course of advanced non-professional study. In 1909–10 there were about ninety professors and instructors and 1040 students. The college had in 1909 total productive funds of about $1,360,000, yielding an income of about $600,000. James Monroe Taylor (b. 1848), a graduate of the university of Rochester and of Rochester Theological Seminary, became president of the college in 1886.

See Benson J. Lossing's *Vassar College and its Founder* (New York, 1867) and Frances A. Wood's *Earliest Years at Vassar* (Poughkeepsie, N.Y., 1909).

VASTO (anc. *Histonium*), a fortified town of the Abruzzi, Italy, in the province of Chieti, situated high on an olive-clad slope, about a mile from the Adriatic, 32 m. direct S.E. by E. of Chieti and 131 m. by rail from Ancona, 525 ft. above sea-level. Pop. (1901), 10,090 (town); 15,542 (commune). It is surrounded by medieval walls, and commands fine views extending to the Tremiti Islands and Monte Gargano. The churches of S. Pietro and S. Giuseppe have Gothic façades. There is a medieval castle. The municipal buildings contain a collection of Roman antiquities and inscriptions. There are manufactures of earthenware, woollen cloth and silk; but the inhabitants are chiefly employed in the culture of the olive and in fishing.

The ancient *Histonium* was a town of the Frentani, and an Oscan inscription of the period of its independence speaks of censors there, probably officers of the whole community of the Frentani (see R. S. Conway, *Italian Dialects*, i. 208, Cambridge, 1897). Though hardly mentioned in history, it was a flourishing municipal town under the Roman Empire, as is shown by the numerous inscriptions found there. One of these mentions its Capitolium or temple of Jupiter, Juno and Minerva. It lay on the line of the ancient road which prolonged the Via Flaminia to the S.E., and reached the coast here after having passed through Anxanum (Lanciano). It was, and still is, subject to severe earthquakes. (T. As.)

VATICAN COUNCIL, THE, of 1869 and 1870, the last ecumenical council of the Roman Catholic Church, and the most important event in her historical development since the Tridentine synod. The preliminaries were surrounded by the closest secrecy. As early as the end of the year 1864, Pius IX. had commissioned the cardinals resident in Rome to tender him their opinions as to the advisability of a council. The majority pronounced in favour of the scheme, dissentient voices being rare. After March 1865 the convocation of the council was no longer in doubt. Thirty-six carefully selected bishops of diverse nationalities were privately interrogated with regard to the tasks which, in their estimation, should be assigned to the prospective assembly. Some of them proposed, *inter alia*, that the doctrine of papal infallibility should be elevated to the rank of a dogma. In public, however, Pius IX. made no mention of his design till the 26th of June 1867, when Catholic bishops from every country were congregated round him in Rome on the occasion of the great centenary of St Peter. On the 29th of June 1868 the bull *Aeterni Patris* convened the council to Rome, the date being fixed for the 8th of December 1869. And since the Roman Catholic Church claims that all baptized persons belong to her, special bulls were issued, with invitations to the bishops of the Oriental Churches, to the Protestants and to the other non-Catholics, none of which groups complied with the request.

The object of the council was long a mystery. The Bull of Convocation was couched in perfectly general terms, and specified no definite tasks—a circumstance which at first ensured a favourable reception for the scheme, as it allowed ample scope to hope and imagination. But, among liberal Catholics, this mood underwent a complete reversal when information began to leak out as to the object of the Curia in convening the council. The first—epoch-making—revelation was given, in February 1869, by an article in the *Civiltà Cattolica*, a periodical conducted under Jesuit auspices. It was there stated, as the view of many Catholics in France, that the council would be of very brief duration, since the majority of its members were in agreement. As a presumptive theme of the deliberations, it mentioned *inter alia* the proclamation of papal infallibility. The whole proceeding was obviously an attempt, from the Jesuit side, to gauge the prevalent opinion with regard to this favourite doctrine of ultramontanism. The repudiation was energetic and unmistakable, especially in Germany. Certain articles on "The Council and the Civiltà," published by Döllinger in the *Allgemeine Zeitung*, worked like a thunderbolt. Unions of the laity, designed to repel the encroachments of ultramontanism, sprang up immediately; and all manner of old ideas for the remodelling of the clergy were broached anew. It must, however, be admitted that counter demonstrations were not lacking. The attitude adopted by the German episcopate well exemplifies the ecclesiastical situation of that period. The bishops tried to allay the excitement by publishing a pastoral letter drawn up in common; but in a written address to the pope they declared against the contemplated definition of infallibility. In France also a violent conflict broke out. Here it was principally the writings of Bishop Maret in Paris (*Du concile général et de la paix religieuse*, 2 vols., 1869), and of Bishop Dupanloup of Orleans, which gave expression to the prevalent unrest, and led to those literary controversies in which Archbishop Manning of Westminster and Dechamps of Mechlin came forward to champion the opposite cause. In Italy the free-thinkers considered the moment opportune for renewing their agitations on a larger scale. They even attempted—though with no success worth the name—to counteract the Vatican Council by a rival council in Naples. That the projected dogma had weighty opponents among the higher clergy of Austria-Hungary, Italy and North America was demonstrated during the progress of the council; but before it met all was quiet in these countries. The credit of inviting the European governments to consider their attitude towards the forthcoming synod belongs to the president of the Bavarian ministry, Prince Chlodwig of Hohenlohe-Schillingsfürst, the future imperial chancellor. In his circular note to the Powers of the 9th of April 1869 he analysed the political import of the doctrine of papal infallibility,[1] and proposed a common course of action. But his overtures met with no response. In view of the strained international situation, none of the Powers approached was willing to take a step which might easily have resulted in a bitter conflict with the Church; and the studied vagueness of the Curia in its official pronouncements on the council enabled them to assume an attitude of reserve and suspension of judgment. France was equally inactive, though it rested with her to decide whether the council could even meet in Rome: for the withdrawal of her troops from the papal state would have been the signal for a patriotic Italy to sweep this last impediment to national unity from the face of the earth.

On none of the previous ecumenical councils did the Roman see exercise so pronounced an influence as on the Vatican. As early as the year 1865 a committee of cardinals had been formed as a "special directive congregation for the affairs of the future general council," a title which was usually abbreviated to that of "Central Commission." Among the earliest preliminaries, a number of distinguished theologians and canonists were retained as *consultors* to the council. In the selection of these the preference for men of ultramontane tendencies was so pronounced—Döllinger, for instance, was not invited—that the influences at work in the convocation of the council were obvious long before its opening. Under the control of the Central Commission were six sub-commissions: (1) for dogma; (2) for matters of ecclesiastical discipline; (3) for the religious orders; (4) for the Oriental Churches and the missions; (5) for the secular policy of the Church;

[1] The note was drafted by Döllinger (see INFALLIBILITY).

(6) for the ceremonial of the council. The pope nominated the presidents of the council (Cardinals Reisach, de Luca, Bizarri, Bilio and Capalti); also the secretaries and the remaining officials. Again, before the proceedings began, he determined the order of business on his own initiative (*Multiplices inter d. d.* Nov. 27, 1869),—thus precluding the members of the synod from any opportunity of co-operating in the task. In these regulations the right of fixing the subjects for debate was reserved to the pope. The members of the synod, it is true, enjoyed the privilege of proposing motions; but these motions could never reach the stage of discussion, except by the papal sanction. Another fact of great importance was the strict privacy in which the labours of the council were to be conducted, the members being pledged to silence on every point. For their deliberations, two forms of assembly, analogous to those employed at Trent, were instituted: the *congregationes generales* and the *sessiones*. The General Congregations, presided over by cardinals, were employed in considering the *schemata* (drafts) submitted to the synod; and provisory votes—not regarded as binding—were there taken. The sessions witnessed the definitive voting, the results of which were to be immediately promulgated as ecclesiastical law by the pope. The form of this promulgation was, in itself, sufficiently characteristic; for the pope was represented as the real agent, while the acknowledgment of the share of the council was confined to the phrase *sacro approbante concilio*. In contrast to this, we may refer to the synods of Constance and Trent (C. Mirbt, *Quellen u.s.w.*, pp.155–202, and the articles CONSTANCE, COUNCIL OF, and TRENT, COUNCIL OF). In the event of the drafts submitted by the Curia not being unanimously adopted by the General Congregations, they were to be remitted, together with the objections raised, to special committees chosen from the body of the council. These committees (*congregationes speciales deputationes*), the presidents of which were also nominated by the pope, were four in number: (1) for matters of belief; (2) for questions of ecclesiastical discipline; (3) for the religious orders; (4) for affairs of the Oriental Churches. The whole proceedings took place in the church of St Peter, the south transept of which had been prepared especially for the purpose. That the acoustic properties of the structure were unequal to the demands made upon them was obvious from the first day, and occasioned numerous complaints.

On the 8th of December the first session met, and the council was solemnly opened by Pius IX. From beginning to end it was dominated by the " Infallibility " problem. At the elections to the committees the fact was already obvious; for the leaders of the synodal majority in favour of the dogma took excellent care that no one should be chosen who was known to lean toward the opposite side. The order of procedure excited considerable dissatisfaction in many; and a series of petitions, with alternative suggestions, was submitted to the pope, but without success. The very first transactions of the council gave proof that numerous bishops held the theory that their convocation implied the duty of serious and united work, and that they were by no means inclined to yield a perfunctory assent to the papal propositions, which—in part at least—stood in urgent need of emendation. The Curia awoke to this unpleasant fact during the discussion upon the first draft laid before the council,—the schema *De Fide*,—and some perplexity was the result; for on the 8th of December the second session had already been announced for the 6th of January. Since the consideration of the *schema* could not possibly be completed by that date, and since it was now futile to hope that the doctrine of infallibility would be carried by acclamation, and without debate, in that session,—Archbishop Darboy informing Cardinal de Luca that, in this event, a hundred bishops would leave Rome at once,—the second session, on the 6th of January, was reduced to a mere formality, the delegates again declaring their allegiance to the *Professio Fidei Tridentinae*, to which they had already pledged themselves at ordination. On the 10th of January the schema *De Fide* was referred to the committee " for matters of belief," to receive further revision.

From the 10th of January to the 22nd of February 1870 the council was occupied with proposals concerning ecclesiastical discipline and with questions of church life. On this occasion it became evident that the synod was not blind to the necessity for many and various reforms. Even the College of Cardinals and the Curia did not escape. Complaint was made, for instance, that the papal chair and the Roman Congregations were filled almost exclusively by Italians; while the control of the Church was too much centralized in Rome. Again, the treatment of impediments to marriages, of licences and of the scales of charges, was submitted to criticism. The fact was elicited that the resolutions of provincial synods, when transmitted to Rome for approbation, were there subjected to arbitrary changes, so that the contents no longer corresponded with those to which the bishops had affixed their signatures. Even the desire for national assemblies and for ecumenical councils, held at regular intervals, found expression. The delicate subject of the compulsory celibacy of the clergy was also discussed; the notorious defects of the Roman Breviary were considered, and a long debate ensued with regard to the policy of drawing up a short catechism for the whole of Catholic Christendom. Even the proposals which led to these declarations of opinion—many of which were neither anticipated nor desired—were not accepted by the council, but returned for revision to the respective committees.

That matters progressed slowly was undeniable. It was the third month, and not one of the proposals under consideration had been despatched. That this unexpected delay was a natural sequel to the character of the proposals themselves was a fact which the Curia declined to recognize. Consequently, as that body could rely upon a complacent majority, it resolved to proclaim a new order of procedure, by means of which it would be possible to end these unwelcome discussions and quicken the pace of the council. By the papal decree of the 20th of February the influence of the committees was increased; the majority was allowed to cut short a debate by accepting a motion for its closure; a plurality of votes was declared sufficient to carry a proposal; and the voting itself was modified by the institution of a " conditional affirmative " (*placet iuxta modum*) in addition to the regular affirmative and negative (*placet* and *non placet*). Since neither the presidents nor the majority of the council could well be expected to employ the extensive powers thus placed at their disposal with much consideration for the rights of the minority, protests by the weaker party against the new regulations were handed in to the pope, but to no effect.

The main object, however, of this alteration in procedure was to ensure that if the council could not be induced to accept the doctrine of infallibility by acclamation, it should at least do so by resolution. From the first the general interest was almost exclusively concentrated on this question, which divided the members of the synod into two hostile camps. The adherents of the contemplated dogma—among whom Archbishop Manning of Westminster and Bishop Senestrey of Regensburg admittedly held the leading position—circulated petitions to the pope requesting the introduction of a proposal to meet their views; and, as a result of their efforts, the signatures of 480 bishops were obtained. This manœuvre aroused the other side. Petitions to the opposite effect were now similarly distributed, and signed by 136 bishops. On the 9th of February the committee of examination—as was only to be expected—resolved to recommend the pope to grant the wishes of the majority. The remarkable feature of the situation created by these agitations was not that the majority of members declared in favour of the dogmatization of infallibility—that was a foregone conclusion in view of the strides made by ultramontanism in the Roman Catholic Church—but that so many could be found with courage enough to withstand the aspiration to which Pius IX. had given open expression on every possible occasion. The weight of their opposition was accentuated by the fact that the finest intellects and the ablest theologians of Catholicism were included in their ranks. The presence of striking personalities, whose devotion to the Church was beyond question, —Archbishop Scherr of Munich, Melchers of Cologne, Bishop

Ketteler of Mainz, Bishop Hefele of Rottenburg, Cardinal Schwarzenberg of Prague, Cardinal Rauscher of Vienna, Archbishop Haynald of Kalossa, Bishop Strossmayer of Sirmium, Archbishop Darboy of Paris, Bishop Dupanloup of Orleans, to say nothing of the others,—assured this group an influence which, in spite of itself, the opposing faction was bound to feel. If the minority indeed had formed one compact phalanx, the council might possibly have taken a different course; but this it was not, and the fatal truth could not be concealed from the pope and his advisers. The bond which united its members was not a repudiation of the doctrine of infallibility itself, but simply a common sentiment that its elevation to the rank of dogma was inopportune *at the time.* Some—possibly many—may have entertained serious doubts with regard to that doctrine; but, if such was the case, they succeeded in repressing and disciplining their suspicions, and the greatest anxiety was shown to avoid the least attempt at founding their resistance on a dogmatic basis. And here the weakness of the opposition is at once manifest; it lacked a clear and positive goal.

In outside circles the proceedings at Rome were followed with strained attention, and the battle round the question of infallibility was waged with equal violence in France and Germany. In the one country public interest was focused on the writings of Gratry, the former Oratorian; in the other on the trenchant attacks of Döllinger. In England, Newman protested against the dogma. The progress of the council was marked by a plethora of controversial literature with which it was almost impossible to keep pace; articles and pamphlets were poured forth in increasing volume month after month, and even yet no classified collection of them is extant. Among them all, none exceeded in influence the *Römische Briefe*, first published in the Augsburg *Allgemeine Zeitung*, which gave a regular account of the most intimate transactions of the council, and maintained a high reputation for accuracy in spite of all attempts to discredit their authenticity. Important service in disseminating information among widely extended circles was done by the brochure *Ce qui se passe au concile* (May 1870), which revealed a number of proceedings never intended for publicity.

Among the secret propositions submitted to the council by the Curia was the schema *De Ecclesia Christi*, which was distributed to the members on the 21st of January. This contained fifteen sections, in which were defined the nature of the Church, the position of the pope in the Church, and, more especially, the relationship between the Church and the State. In case the harmony between these two magnitudes is disturbed, the responsibility lies with the State, because it thereby disregards the rights and duties of the Church (cap. 13). The divine law is binding on temporal sovereigns, but the administration of that law is a question which can only be decided by the supreme doctrinal authority of the Church (cap. 14). In addition to the education of youth, the Church demands absolute freedom in the training of its clergy and the abrogation of all restrictions on the religious orders, &c. Thus the superiority of Church to State was here enunciated in the same drastic terms as in the *Syllabus* of Pius IX. (1864)—a declaration of war against the modern political and social order, which in its day provoked the unanimous condemnation of public opinion. When, in spite of the injunction of secrecy, the schema became known outside Rome, its genuineness was at first impugned; but as soon as the authenticity of the text was established beyond the possibility of doubt, this attempt to dogmatize the principles of the notorious *Syllabus* excited the most general indignation, even in the strongholds of Catholicism—France and Austria. It almost appeared as if both governments, incensed by these encroachments on the sphere of the State, were at last bent upon bringing pressure to bear on the future deliberations of the council; but the international situation enabled the Curia to persist in its attitude of strict negation towards the despatches of Count Beust and Count Daru. On political grounds Napoleon was not inclined to employ any form of coercion against the synod; Bismarck maintained a like reserve; and although Lord Acton influenced Gladstone in the contrary direction, Lord Clarendon followed Odo Russell, his *chargé d'affaires* in Rome, who was himself adroitly kept in hand by Manning. Thus the danger that the attitude of the secular powers might imperil the liberties of the council was averted for the second time.

From the 22nd of February to the 18th of March no meetings of the General Congregations took place, on account of structural alterations in the *aula* itself. During this interval all uncertainty as to whether the question of infallibility would actually be broached was dispelled. On the 6th of March a supplementary article to section 11 of the schema *De Ecclesia*, dealing with the primacy of the Roman see, was transmitted to the members, and in it the much disputed doctrine received formal expression. But before the animated discussions which centred round this problem could begin, it was imperative to conclude the debate on the schema *De Doctrina Catholica.* From the deputation "for matters of faith" it returned to the *plenum* in a considerably modified form, and there it occupied the attention of the assembly for a full month, beginning with the 18th of March. Even in this later stage it frequently gave rise to trenchant criticism; but the greatest sensation was created by a speech of Bishop Strossmayer, who took exception to the terms of the proposal on the ground that it described Protestantism as the fountain-head of naturalism and as an unclean thing (*pestis*). There followed a dramatic scene: the orator was interrupted by the president and compelled by the outcries of the indignant fathers to quit the tribune. Nevertheless, Strossmayer by his courageous protest succeeded in modifying the objectionable clauses. The bishops of the minority were still dissatisfied with several passages in the *schema*, but, desirous of concentrating their whole available force in opposition to the next proposal, they suppressed their doubts; and the result was that, on the 24th of April, in the third public session, the *Constitutio dogmatica de Fide Catholica*[1] was adopted unanimously and immediately confirmed by the pope.

Meanwhile, the elaboration of the all-important business of the council had been quietly proceeding. Influenced by the alarming number of amendments to the schema *De Ecclesia*, and anxious above all to ensure an early acceptance for the dogma of infallibility, the deputation abandoned the idea of subjecting the entire doctrine of the Church to debate, and resolved to eliminate everything save the one question of papal authority, and to submit this to the council alone. That this procedure directly challenged criticism was obvious enough, and, within the synod, several speakers drew attention to the capriciousness of a method which required them to consider the infallibility of the pope before the nature of the Church herself had been defined. The event, however, justified the wire-pullers of the council in their policy, for the path they chose obviated the danger that the discussion might lose itself in a maze of generalities. It is impossible to give a short and, at the same time, an adequate account of the debate: lengthy disquisitions were the order of the day, and the disputants did not scruple to indulge in verbose repetition of arguments worn threadbare by their predecessors. A pleasant impression is left by the great candour of the opposition speakers, who, in the course of the next few weeks, made every point against the doctrine which in their position it was possible to make. In the general debate, begun on the 13th of May, Bishop Hefele of Rottenburg, author of the well-known *Konziliengeschichte*, criticized the dogma from the standpoint of history, adducing the fact that Pope Honorius I. had been condemned by the sixth ecumenical council as a heretic (680). Others were of opinion that the doctrine implied a radical change in the constitution of the Church: one speaker even characterized it as sacrilege. The contention that the dogma was necessitated by the welfare of the Church, or justified by contemporary conditions, met with repeated and energetic repudiation. The champions of infallibility were, indeed, confronted with no slight task:—to establish their theory by Holy Writ and tradition, and to defend it against the arguments of history.

[1] Mirbt, *Quellen*, 371–77.

But to them it was no hypothesis waiting to be verified, but an already existing truth, the possession of which no extraneous attacks could for a moment affect. On the 3rd of June the general debate was closed, and forty prospective orators compulsorily silenced.

In the special debate, which dealt with the proposal in detail, every important declaration with regard to the pope was impugned by one party and upheld by the other. The main assault was naturally directed upon the fourth section, "concerning the doctrinal authority of the pope," and Archbishop Guidi of Bologna, in particular, incurred the resentment of the majority through his outspoken utterances on the subject. Immediately after the session he was summoned to the Vatican, and, on defending his attitude by an appeal to tradition, received from Pius IX. the celebrated answer, "I am the tradition." From the beginning of July onwards it became increasingly evident that the council was on the verge of exhaustion: the great heat was positively dangerous to members accustomed to a colder climate, and the opinion gained ground that the spokesmen of both parties had sufficiently elucidated their views for the benefit of the conclave. Many delegates who had announced their intention of speaking relinquished the privilege, and on the 13th of July it was found possible to conclude the debate. On that day the voting in the 85th General Congregation, on the whole schema, showed that, out of 601 members present, 451 had voted *placet*, 88 *non placet* and 62 *placet iuxta modum*. That the number of prelates who rejected the *placet* would amount to 150 had not been expected. The question was now: Could the doctrine of infallibility be raised to dogmatic rank when it was repudiated by so formidable a minority? At the height of the crisis several leaders of the opposition attempted, by a direct appeal to the pope, to secure a modification in the terms of the dogma, which might enable them to give their assent. On the evening of the 15th of July six bishops were accorded an audience with Pius IX., in which they preferred their modest requests. Ketteler threw himself at the feet of the pope and implored him to restore peace to the Church by a little act of compliance. The touching scene appeared to have made some impression on Pius IX.; but, after the deputation had left, opposing influences gained the ascendant, and the result was simply that the clauses on which everything hinged received an addition the reverse of conciliatory (General Congregation, 16th July). The bishops who had hitherto formed the recalcitrant minority were now face to face with the final decision. On the one hand was their loyalty to the pope, allied with the desire to avoid any demonstration calculated to impair the prestige of the Church; on the other, their conviction that the very doctrine which the council was about to proclaim as dogma was a gigantic error. There was but one way out of the *impasse*,—to leave Rome before the deciding session,—and on the 16th of July the pope met their wishes and accorded the leave of absence previously withheld. A section of the dissentient bishops reiterated their views in a letter to Pius IX., and agreed to direct their subsequent actions in common,—a compact which was not observed. On the 18th of July, in the fourth public session, the dogma was accepted by 535 dignitaries of the Church, and at once promulgated by the pope; only two members repeated their *non placet*, and these submitted in the same session. The council continued its labours for a few more weeks, but its main achievement was over, and the remainder of its time was occupied with affairs of secondary importance. When, coincident with the outbreak of the Franco-German War, the papal state collapsed, the pope availed himself of the altered situation, and prorogued the council by the bull *Postquam Dei munere* (October 20). The Italian government at once protested against his statement that the liberties of the council would be prejudiced by the incorporation of Rome into the kingdom of Italy.

The resolutions of the Vatican Council entirely revolutionized the position of the pope within the Church. He is first accredited with "complete and supreme jurisdictionary authority over the whole Church, not simply in matters of faith and morality, but also in matters touching the discipline and governance of the Church; and this authority is a regular and immediate authority, extending over each and every Church and over each and every pastor and believer" (*Sessio* iv. cap. 3, *fin.*; Mirbt, *Quellen*, p. 380). These words conceded to the pope a universal episcopate in the entire Church, in virtue of which he may, at any time, in any diocese, exercise the functions of the regular bishop: the individual bishop forfeited the independence which he had formerly enjoyed, and the episcopate as a whole was dispossessed of that position which, in preceding centuries, had enabled it to champion the true welfare of the Church against a decadent papacy. Nor was this all: it is laid down "as a dogma revealed by God, that the Roman pontiff, when he speaks *ex cathedra*,—that is to say, when, in virtue of his supreme apostolical authority, and in the exercise of his office as pastor and instructor of all Christians, he pronounces any doctrine touching faith or morality to be binding on the whole Church,—is, by reason of the divine assistance promised to him in the person of St Peter, endowed with that infallibility which, according to the will of the Redeemer, is vouchsafed to the Church when she desires to fix a doctrine of faith or morality; and that consequently all such decisions of the Roman pontiff are *per se* immutable and independent of the subsequent assent of the Church. But if any man,—which Heaven forefend!" proceeds the document, "shall venture to deny this definition, let him be accursed!" (*Sessio* iv. cap. 4; Mirbt, *Quellen*, p. 381). These clauses contain the doctrine of papal infallibility, and make the recognition of that doctrine incumbent on all Catholic Christians. But how are we to recognize whether the decision of the pope is given "in the exercise of his doctrinal office," or not? No criterion is assigned, and no authentic interpretation has been accorded from the chair of St Peter. Thus great uncertainty prevails with regard to utterances *ex cathedra*; and the result has been that every papal declaration has tended to be invested with the halo of infallibility. Again, the dogma implies a fundamental change in the position of the ecumenical councils, which, in conjunction with the papacy, had till then been supposed to constitute the representation of the Roman Catholic Church. By the *Vaticanum* they lost every vestige of actual, independent authority, for their function of defining the doctrine of the Church now passed to the pope; and, though in the future they may still be convened, their indispensability is a thing of the past. They have ceased to form a constituent organ of the Church, and are sunk to the level of a decorative or consultative assembly. Thus the decrees of the council possess a double significance; they have not only erected the papacy into the sole tribunal for questions of belief, but have at the same time radically transformed the constitution of the Church. The two factors which previously served to check the papal ambition have been shorn of their strength, and the papacy has attained the status of an absolute monarchy. The concurrent loss of the papal states, so far from enfeebling this new absolutism, tended, in spite of the protests of the Curia, to increase its strength, for its position now became unassailable, and it was enabled to concentrate its energies on a purely international policy to a greater extent than formerly.

The bishops, who, on the council, had impugned the doctrine of papal infallibility, submitted without exception to the promulgated dogma. Confronted with the alternative of either seceding from the Church or adopting a theory which they had previously attacked, they resorted to the "sacrifice of reason," many with bleeding hearts; many, as it would seem, without any pangs of conscience. But though they submitted they failed to carry with them the whole of the theologians and laymen who had ranged themselves at their side in the battle against the dogma; and after the conclusion of the council a new Church was formed, which, in contrast with the *fin de siècle* Catholicism which, by the Vatican Synod, had cut itself loose from the traditions of the past, was termed Old Catholic (see the special article).

In the sphere of politics also the *Vaticanum* was attended by important results. The secular governments could not remain indifferent to the prospect that the proclamation of papal infallibility would invest the *dicta* of the medieval popes, as to the relationship between Church and State, with the character of inspired doctrinal decisions, and confer dogmatic authority on the principles enunciated in the *Syllabus* of Pius IX. Nor was the fear of these and similar consequences diminished by the proceedings of the council itself. The result was that on the 30th of July 1870, Austria annulled the Concordat arranged with the Curia in 1855. In Prussia the so-called *Kulturkampf* broke out immediately afterwards, and in France the synod so accentuated the power of ultramontanism, that, in late years, the republic has taken effectual steps to curb it by revoking the Concordat of 1801 and completely separating the Church from the State.

The antecedent history of the council was long; its subsequent history is a chapter which has not yet been closed. That the dogma was carefully prepared beforehand, mainly by the Society of Jesus, is a demonstrable and demonstrated fact, notwithstanding the denials emanating from writers belonging to the society.

The general position of Roman Catholicism was consolidated by the Vatican Council in more respects than one; for not only did it promote the centralization of government in Rome, but the process of unification soon made further progress, and the attempts to control the intellectual and spiritual life of the Church have now assumed dimensions which, a few decades ago, would have been regarded as anachronistic. On the other hand, however, a counter-movement can be traced in all countries with a predominant Catholic population,—the so-called Reformed Catholicism, which may wear a different aspect in different districts and different strata of society, but is everywhere distinguished by the same fundamental aspiration towards increased liberty. Thus the victory gained by ultramontane influences within the Church—a victory for which the *Vaticanum* was largely responsible—closes one period of development, but a second has already begun, the keynote of which is the search for a *modus vivendi* between this Vatican system and the Catholicism which is rooted in the intellectual life of the modern world.

Bibliography.—A résumé of the literature bearing on the history of this council is given by C. Mirbt in the *Realencyclopädie*, vol. xx. 445 seq. (ed. 3, Leipzig, 1908). The two most detailed accounts are: J. Friedrich, *Geschichte des Vatikanischen Konzils* (3 vols., Bonn, 1877, 1883, 1887); and Th. Granderath, S.J., *Geschichte des Vatikanischen Konzils* (ed. K. Kirch, 3 vols., Freiburg im Breisgau, 1903–6). The last-mentioned work represents the Jesuitico-Curial standpoint (cf. C. Mirbt, "Die Geschichtschreibung des Vatikanischen Konzils," *Historische Zeitschrift*, Band 101, 1908, pp. 529–600). The most important collections of the *acta* are: *Collectio Lacensis*, tome vii. (Freiburg, 1890); E. Friedberg, *Sammlung der Aktenstücke zum ersten Vatikanischen Konzil* (Tübingen, 1872); J. Friedrich, *Documenta ad illustrandum Concilium Vaticanum* (Nördlingen, 1871); A. v. Roskovany, *Romanus Pontifex*, tomes 7–16, Suppl. 7–10 (Nitriae, 1871–79). For the dogmatic resolutions see also C. Mirbt, *Quellen zur Geschichte des Papsttums* (ed. 2, Tübingen, 1901), pp. 371–82. For the internal history of the councils one of the main sources is Quirinus, *Römische Briefe vom Konzil* (Munich, 1870). Also, J. Friedrich, *Tagebuch während des Vatikanischen Konzils* (Nördlingen, 1871); Lord Acton, *Zur Geschichte des Vatikanischen Konziles* (Munich, 1871, Eng. in *Hist. Essays*, 1907); J. Fessler, *Das Vatikanische Concilium* (Vienna, 1871); Manning, *The True Story of the Vatican Council* (London, 1877); E. Ollivier, *L'Église et l'état au concile du Vaticân* (2 vols., Paris, 1879); Purcell, *Life of Cardinal Manning* (2 vols., London, 1896). Cecconi's great work, *La Storia del Concilio ecumenico Vaticano* (4 vols., Rome, 1873–79), is incomplete. For criticism of the council, see Janus, *Der Papst und das Konzil* (Leipzig, 1869), revised by J. Friedrich under the title *F. v. Döllinger, Das Papsttum* (Munich, 1892). Also, Gladstone's *Vatican Decrees and Vaticanism* (London, 1874). (C. M.)

VATKE, JOHANN KARL WILHELM (1806–1882), German Protestant theologian, was born at Behndorf, near Magdeburg, on the 14th of March 1806. After acting as *Privatdozent* in Berlin, he was appointed in 1837 professor extraordinarius. Vatke was one of the founders of the newer Hexateuch criticism. In the same year in which David Strauss published his *Life of Jesus*, Vatke issued his book, *Die Religion des Alten Testaments nach den kanonischen Büchern entwickelt*, which contained the seeds of a revolution in the ideas held about the Old Testament. Since, however, his book was too philosophical to be popular, the author's theories were practically unnoticed for a generation, and the new ideas are now associated especially with the names of A. Kuenen and J. Wellhausen (*qq.v.*). He died on the 18th of April 1882.

His other works include: *Die menschliche Freiheit in ihrem Verhältniss zur Sünde und zur göttlichen Gnade* (1841), *Historisch-kritische Einleitung in das Alte Testament* (1886), and *Religionsphilosophie* (1888). See O. Pfleiderer, *Development of Theology* (1890), and T. K. Cheyne, *Founders of Old Testament Criticism* (1893).

VATTEL, EMERIC (Emer) **DE** (1714–1767) Swiss jurist, the son of a Protestant minister, was born at Couvet, in the principality of Neuchâtel, on the 25th of April 1714. He studied at Basel and Geneva. During his early years his favourite pursuit was philosophy; and, having carefully examined the works of G. W. Leibnitz and C. Wolff, he published in 1741 a defence of Leibnitz's system against J. P. de Crousaz. In the same year Vattel, who was born a subject of the king of Prussia, repaired to Berlin in the hope of obtaining some public employment from Frederick II., but was disappointed in his expectation. Two years later he proceeded to Dresden, where he experienced a very favourable reception from Count Brühl, the minister of Saxony. In 1746 he obtained from the elector, Augustus III., the title of councillor of embassy, accompanied with a pension, and was sent to Bern in the capacity of the elector's minister. His diplomatic functions did not occupy his whole time, and much of his leisure was devoted to literature and jurisprudence. Among other works he published *Loisirs philosophiques* (1747) and *Mélanges de littérature, de morale, et de politique* (1757). But his reputation chiefly rests on his *Droit des gens, ou Principes de la loi naturelle appliqués à la conduite et aux affaires des nations et des souverains* (Neuchâtel, 1758). During the same year he was recalled from Switzerland, to be employed in the cabinet of Dresden, and was soon afterwards honoured with the title of privy councillor. His labours now became so intense as to exhaust his strength, and his health broke down. After a period of rest he returned to Dresden in 1766; but his renewed exertions soon produced a relapse, and he made another excursion to Neuchâtel, where he died on the 28th of December 1767. His last work was entitled *Questions de droit naturel, ou Observations sur le traité du droit de la nature, par Wolff* (Bern, 1762).

Vattel's *Droit des gens*, which is founded on the works of Wolff, had in its day a great success, in truth, greater than it deserved. His principal and only merit consists in his having rendered the ideas of that author accessible to the political and diplomatic world. The *Droit des gens* passed through many editions, and was translated into various languages (English in 1760).

VAUBAN, SÉBASTIEN LE PRESTRE DE (1633–1707), marshal of France, the most celebrated of military engineers (see Fortification), was born at Saint-Léger-Vauban (Yonne). At the age of ten he was left an orphan in very poor circumstances, and his boyhood and youth were spent amongst the peasantry of his native place. A fortunate event brought him under the care of the Carmelite prior of Sémur, who undertook his education, and the grounding in mathematics, science and geometry which he thus received was of the highest value in his subsequent career. At the age of seventeen Vauban joined the regiment of Condé in the war of the Fronde. His gallant conduct won him within a year the offer of a commission, which he declined on account of poverty. Condé then employed him to assist in the fortification of Clermont-en-Argonne. Soon afterwards he was taken prisoner by the royal troops; but though a rebel he was well treated, and the kindness of Mazarin converted the young engineer into a devoted servant of the king. He was employed in the siege of St Ménéhould (which he had helped to storm as a Frondeur) and won a lieutenancy in the regiment of Burgundy, and at Stenay he was twice wounded. Soon afterwards he besieged and took his own first fortress, Clermont; and in May 1655 he received his commission as an *ingénieur du roi*, having served his apprenticeship under the Chevalier de Clerville, one of the foremost engineers of the time. Between that year and the peace of 1659 he had taken part in or directed ten sieges with distinction, had been several times wounded, and was rewarded by the king with the free gift of a company in the famous Picardy regiment. About this time he married a cousin, Jeanne d'Aulnay. After the peace Vauban was put in charge of the construction of several important defences, amongst other places at Dunkirk, where his work continued until the year before his death. On the renewal of war in 1662 he conducted, under the eyes of the king, the sieges of Douai, Tournai and Lille. At Lille he so distinguished himself that he received a lieutenancy in the guard (ranking as a colonelcy).

The peace of Aix-la-Chapelle confirmed France in the possession of new fortresses, which Vauban now improved or rebuilt. Hitherto the characteristic features of his method of fortification had not been developed, and the systems of preceding engineers were faithfully followed. Colbert and Louvois were profoundly interested in the work, and it was at the request of the latter that the engineer drew up in 1669 his *Mémoire pour servir à l'instruction dans la conduite des sièges* (this, with a memorandum on the defence of fortresses by another hand, was published at Leiden in 1740). On the renewal of war Vauban again conducted the most important sieges (Rheinbergen and Nijmwegen 1672, Maestricht and Trier 1673, Besançon 1674). In the latter year he also supervised the only defence in which he ever took part, that of Oudenarde. This was followed by the reduction of Dinant, Huy and Limburg. At this time he wrote for the commandants of Verdun and Le Quesnoy, valuable *Instructions pour la défense* (MS. Dépôt des Fortifications, Paris; see also Quincy, *Art de la guerre*, Paris, 1740). In 1676 he was made *maréchal de camp*. He took Condé, Bouchain and other places in that year, Valenciennes and Cambrai in 1677, Ghent and Ypres in 1678.

It was at this time that Vauban synthesized the methods of attacking strong places, on which his claim to renown as an engineer rests far more than on his systems of fortification. The introduction of a systematic approach by parallels (said to have been suggested by the practice of the Turks at Candia in 1668) dates from the siege of Maestricht, and in principle remains to this day the standard method of attacking a fortress. The peace of Nijmwegen gave more territory to France, and more fortresses had to be adapted. Vauban was named *commissaire-général des fortifications* on the death of De Clerville, and wrote in 1679 a memorandum on the places of the new frontier, from which it appears that from Dunkirk to Dinant France possessed fifteen fortresses and forts, with thirteen more in second line. Most of these had been rebuilt by Vauban, and further acquisitions, notably Strassburg (1681), involved him in unceasing work. At Saarlouis for the first time appeared Vauban's "first system" of fortification, which remained the accepted standard till comparatively recent times. He never hesitated to retain what was of advantage in the methods of his predecessors, which he had hitherto followed, and it was in practice rather than in theory, that he surpassed them. In 1682 his "second system," which introduced modifications of the first designed to prolong the resistance of the fortress, began to appear; and about the same time he wrote a practical manual entitled *Le Directeur-Général des fortifications* (Hague, 1683–85). Having now attained the rank of lieut.-general, he took the field once more, and captured Courtrai in 1683, and Luxemburg in the following year. The unexpected strength of certain towers designed by the Spanish engineer Louvigni (fl. 1673) at Luxemburg suggested the tower-bastions which are the peculiar feature of Vauban's second system (see Augoyat, *Mémoires inédits du Ml. de Vauban*, Paris, 1841) which was put into execution at Belfort in the same year (Provost du Vernois, *De la fortification depuis Vauban*, Paris, 1861). In 1687 he chose Landau as the chief place of arms of Lower Alsace, and lavished on the place all the resources of his art. But side by side with this development grew up the far more important scheme of attack. He instituted a company of miners, and the elaborate experiments carried out under his supervision resulted in the establishment of all the necessary formulae for military mining (*Traité des mines*, Paris, 1740 and 1799; Hague, 1744); while at the siege of Ath in 1697, having in the meanwhile taken part in more sieges, notably that of Namur in 1692 (defended by the great Dutch engineer Coehoorn), he employed ricochet fire for the first time as the principal means of breaking down the defence. He had indeed already used it with effect at Philipsburg in 1688 and at Namur, but the jealousy of the artillery at outside interference had hindered the full use of this remarkable invention, which with his other improvements rendered the success of the attack almost certain. After the peace of Ryswick Vauban rebuilt or improved other fortresses, and finally New Breisach, fortified on his "third system"—which was in fact a modification of the second and was called by Vauban himself *système de Landau perfectionné*. His last siege was that of Old Breisach in 1703, when he reduced the place in a fortnight. On the 14th of January of that year Vauban had been made a marshal of France, a rank too exalted for the technical direction of sieges, and his active career came to an end with his promotion. Soon afterwards appeared his *Traité de l'attaque des places*, a revised and amplified edition of the older memoir of 1669, which contains the methods of the fully developed Vauban attack, the main features of which are the parallels, ricochet fire and the attack of the defending personnel by vertical fire (ed. Augoyat, Paris, 1829).

But Louis XIV. was now thrown on the defensive, and the war of the Spanish Succession saw the gradual wane of Vauban's influence, as his fortresses were taken and retaken. The various captures of Landau, his *chef-d'œuvre*, caused him to be regarded with disfavour, for it was not realized that the greatness of his services was rather in the attack than in the defence. In the darkness of defeat he turned his attention to the defence; but his work *De la défense des places* (ed. by General Valazé, Paris, 1829) is of far less worth than the *Attaque*, and his far-seeing ideas on entrenched camps (*Traité des fortifications de campagne*) were coldly received, though therein may be found the elements of the "detached forts" system now universal in Europe. The close of his life, saddened by the consciousness of waning influence and by failing health, he devoted largely to the arrangement of the voluminous manuscripts (*Mes oisivetés*) which contained his reflections on war, administration, finance, agriculture and the like. In 1689 he had had the courage to make a representation to the king in favour of the republication of the Edict of Nantes, and in 1698 he wrote his *Projet d'une dix^me. royale* (see *Economistes financières du XVIII^e siècle*, Paris, 1851), a remarkable work foreshadowing the principles of the French Revolution. Vauban was deeply impressed with the deplorable condition of the peasantry, whose labour he regarded as the main foundation of all wealth, and protested in particular against the unequal incidence of taxation and the exemptions and privileges of the upper classes. His *dix^me. royale*, a tax to be impartially applied to all classes, was a tenth of all agricultural produce payable in kind, and a tenth of money chargeable on manufacturers and merchants. This work was published in 1707, and instantly suppressed by order of the king. The marshal died heart-broken at the failure of his efforts a few days after the publication of the order (March 30, 1707). At the Revolution his remains were scattered, but in 1808 his heart was found and deposited by order of Napoleon in the church of the Invalides.

Vauban's attention was closely engaged, not only in general military matters, but in political and financial reform and the inland navigation of France. He carried out the rearmament of the French infantry with flint-lock muskets and the socket bayonet. The order of St Louis was suggested by him, and lastly may be mentioned the fortress-models which he constructed, most of which are in the Invalides at Paris, and some in the Berlin Zeughaus. The actual total of his work as an engineer is worth recording. He conducted forty sieges and took part in more than three hundred combats, while his skill and experience were employed on the construction or re-building of more than 160 fortresses of all kinds. *Mes oisivetés* long remained unpublished, and of the twelve volumes of manuscript seven are lost. The remainder were published in Paris, 1841–45, in an abridged form, and of the five manuscript volumes three are in public hands, and two belong to the families of two famous engineers, Augoyat and Haxo. At the Hague (1737–1742) appeared, dedicated to Frederick of Prussia, De Hondt's edition of *De l'attaque et défense*, &c., and of this work an improved edition appeared subsequently. But the first satisfactory editions are those of Augoyat and Valazé mentioned above.

VAUCLUSE, a department of south-eastern France, formed in 1793 out of the countship of Venaissin, the principality of Orange, and a part of Provence, and bounded by Drôme on the N., Basses-Alpes on the E., Bouches-du-Rhône (from which it is separated by the Durance) on the S., and Gard and Ardèche (from which it is separated by the Rhone) on the W. It has also an enclave, the canton of Valréas, in the department of Drôme. Pop. (1906) 239,178. Area, 1381 sq. m. The western third of Vaucluse belongs to the Rhone valley, and consists of the rich and fertile plains of Orange, Carpentras and Cavaillon. To the east, with a general west-south-west direction and parallel to one another, are the steep barren ranges of Ventoux, Vaucluse and Lubéron, consisting of limestones and sandstones. The first-mentioned, which is the most northerly, has a maximum elevation of 6273 ft.; the culminating peak, on which is a meteorological observatory, is isolated and majestic. The Vaucluse chain does not rise above 4075 ft. The most southerly range, that of Lubéron (3691 ft.), is rich in palaeontological remains of extant mammals (the lion, gazelle, wild boar, &c.). The Rhone is joined on the left by the Aygues, the Sorgue (rising in Petrarch's celebrated fountain of Vaucluse, which has given its name to the department), and the impetuous Durance. The Sorgue has an important tributary in the Ouvèze and the Durance in the Coulon (or Calavon). These and other streams feed the numerous irrigation canals (Canal de Pierrelatte, Canal de Carpentras, &c.) to which is largely due the success of the farmers and market-gardeners of the department. The climate is that of the Mediterranean region. The valley of the Rhone suffers from the mistral, a cold and violent wind from N.N.W.; but the other valleys are sheltered by the mountains, and produce the oleander, pomegranate, olive, jujube, fig, and other southern trees and shrubs. The mean annual temperature is 55° F. at Orange and 58° at Avignon; the extremes of temperature are 5° and 105° F. Snow is rare. The south wind, which is frequent in summer, brings rain. The average annual rainfall is 29 in. in the hill region and 22 in the plains.

Wheat, potatoes, and oats are the most important crops; sugar-beet, sorghum, millet, ramie, early vegetables and fruits, among which may be mentioned the melons of Cavaillon, are also cultivated, and to these must be added the vine, olive and mulberry. The truffles of the regions of Apt and Carpentras, and the fragrant herbs of the Ventoux range, are renowned. Sheep are the principal live-stock, and mules are also numerous. Lignite and sulphur are mined; rich deposits of gypsum, fire-clay, ochre, &c., are worked. Montmirail has mineral springs of some repute. The industrial establishments include silk mills, silk-spinning factories, oil mills, flour mills, paper mills, wool-spinning factories, confectionery establishments, manufactories of pottery, earthenware, bricks, mosaics, tinned provisions, chemicals, candles, soap and hats, breweries, puddling works, iron and copper foundries, cabinet workshops, blast furnaces, sawmills, edge-tool workshops and nursery gardens. Coarse cloth, carpets, blankets, and ready-made clothes are also produced. The department is served by the Paris-Lyon-Méditerranée railway, and the Rhone is navigable for 40 m. within it. It is divided into 4 arrondissements (Avignon, Apt, Carpentras and Orange), 22 cantons and 150 communes. Avignon, the capital, is the seat of an archbishop. The department belongs to the region of the XV. army corps and to the *académie* (educational circumscription) of Aix, and has its appeal court at Nîmes.

Avignon, Apt, Carpentras, Cavaillon, Orange and Vaison, the most noteworthy towns, are treated separately, and the interesting abbey of Senanque, of Romanesque architecture. Other places of interest are Gordes, with a town hall of Renaissance architecture; Pernes, which has a church of the 11th century and medieval fortifications; La Tour d'Aigues, with fine ruins of the Renaissance château of the barons of Central Bonnieux, near which there is a bridge of the 2nd or 3rd century over the Calavon; Venasque, of Gallo-Roman or even earlier origin, with a baptistery of the 8th or 9th century; and Le Thor, with a fine church in the Provençal Romanesque style.

VAUD (Ger. *Waadt*), one of the cantons of south-western Switzerland. Its total area is 1255·2 sq. m. (thus ranking after the Grisons, Bern and the Valais), of which 1056·7 sq. m. are reckoned as " productive " (forests covering 320·1 sq. m. and vineyards 24·9 sq. m., this last region being more extensive than in any other canton). Of the rest, 160¼ sq. m. are occupied by the portions of various lakes partly in the canton (Geneva, 123½ sq. m.; Neuchâtel, 33 sq. m.; and Morat, 3½ sq. m.) and 4·3 by glaciers, the loftiest point in the canton being the Diablerets (10,650 ft.). The canton is of very irregular shape, as it owes its artificial existence solely to historical causes. It includes practically the whole northern shore of the Lake of Geneva, while it stretches from the " Alpes Vaudoises " and Bex, on the S.E., to the Jura and the French frontier, on the N.W. A long narrow tongue extending past Payerne (Peterlingen) to the Lake of Neuchâtel is just disconnected with the Avenches region that forms an " enclave " in the canton of Fribourg, while in the canton of Vaud, Fribourg holds the two " enclaves " of Vuissens and Surpierre. A small stretch of the right bank of the Rhone (from Bex to the Lake of Geneva) is within the canton, while various short streams flow down into the Lake of Geneva. But the more northerly portion of the canton, beyond the Jorat range, to the north of Lausanne, and in particular the valley of the Broye, belongs to the Aar, and so to the Rhine basin. The canton is thus hilly rather than mountainous, save at its south-eastern extremity. It is well supplied with railways, including that along the northern shore of the Lake of Geneva, while from Bex through Vallorbes runs the main Simplon line towards Paris. There are also numerous " regional " or small-gauge railways, as well as mountain lines from Montreux past Glion up the Rochers de Naye, and from Vevey up the Mont Pèlerin, not to speak of that (" Montreux-Oberland " line) direct to the head of the Sarine valley and so by the Simme valley to the Lake of Thun. In 1900 the population was 281,279, of whom 243,463 were French-speaking, 24,372 German-speaking, and 10,667 Italian-speaking, while 242,811 were Protestants (Calvinists, whether of the larger *église nationale* or of the smaller *église libre*, founded in 1847), 36,980 Romanists, and 1076 Jews. Agriculture is the main occupation of the inhabitants: the land is much subdivided and very highly cultivated.

The vineyards give employment to great numbers of people. Much more white wine is produced than red wine. The best white wines of the canton are Yvorne (near Aigle) and La Côte (west of Lausanne), while the vineyard of Lavaux (east of Lausanne) produces both red and white wine. There is not very much industry in the canton, though at Ste Croix in the Jura watches and musical boxes are made, while at Payerne tobacco is grown. Many foreigners reside in the canton, partly for reasons of health, partly on account of the educational advantages that it offers. They chiefly favour Lausanne, Vevey and the collection of hamlets known as

"Montreux," as well as Châteaux d'Oex, in the upper Sarine valley. Lausanne (*q.v.*) is the political capital of the canton. Next in point of population comes the "agglomeration" known as Montreux (*q.v.*), with 14,144, and Vevey (*q.v.*), with 11,781. Other important villages or small towns are Yverdon (7985 inhab.), Ste Croix (5905 inhab.), Payerne (5224 inhab.), Nyon (4882 inhab.), Morges (4421 inhab.), Aigle (3897 inhab.), and Château d'Oex (3025 inhab.). In educational matters the canton holds a high place. The academy of Lausanne dates from 1537, and was raised to the rank of a university in 1890; and there are a very large number of schools and educational establishments at Morges, Lausanne, Vevey, and elsewhere. Pestalozzi's celebrated institution flourished at Yverdon from 1806 to 1825. Among the remarkable historical spots in the canton are Avenches (the chief Roman settlement in Helvetia), Grandson (*q.v.*) (scene of the famous battle in 1476 against Charles the Bold), and the castle of Chillon (where Bonivard, the prior of St Victor at Geneva, was imprisoned from 1530 to 1536 for defending the freedom of Geneva against the duke of Savoy).

The canton is divided into 19 administrative districts, which comprise 388 communes. The cantonal constitution dates from 1885. The government consists of a *Grand Conseil*, or great council (one member to every 300 electors or fraction over 150), for legislative and a *conseil d'état*, or council of state, of seven members (chosen by the *Grand Conseil*) for executive purposes. In both cases the term of office is four years. Six thousand citizens can compel consideration of any project by the legislature ("initiative," first in 1845), and the *referendum* exists in its "facultative" form, if demanded by 6000 citizens, and also in case of expenditure (not included in the budget) of over half a million francs. The two members of the Federal *Ständerath* are named by the *Grand Conseil*, while the fourteen members of the Federal *Nationalrath* are chosen by a popular vote. Capital punishment was abolished in 1874.

The early history of the main part of the territories comprised in the present canton is identical with that of south-west Switzerland generally. The Romans conquered (58 B.C.) the Celtic Helvetii and so thoroughly colonized the land that it has remained a Romance-speaking district, despite conquests by the Burgundians (5th century) and Franks (532) and the incursions of the Saracens (10th century). It formed part of the empire of Charlemagne, and of the kingdom of Transjurane Burgundy (888–1032), the memory of "good queen Bertha," wife of King Rudolph II., being still held in high honour. After the extinction of the house of Zähringen (1218) the counts of Savoy gradually won the larger part of it, especially in the days of Peter II., "le petit Charlemagne" (d. 1268). The bishop of Lausanne (to which place the see had probably been transferred from Aventicum by Marius the Chronicler at the end of the 6th century), however, still maintained the temporal power given to him by the king of Burgundy, and in 1125 had become a prince of the empire. (We must be careful to distinguish between the present canton of Vaud and the old medieval Pays de Vaud: the districts forming the present canton very nearly correspond to the Pays Romand.) Late in the 15th century Bern began to acquire lands to the south from the dukes of Savoy, and it was out of those conquests that the canton was formed in 1798. In 1475 she seized Aigle and (in concert with Fribourg) Échallens and Grandson as well as Orbe (the latter held of the county of Burgundy). Vaud had been occupied by Bern for a time (1475–1476), but the final conquest did not take place till 1536, when both Savoyard Vaud and the bishopric of Lausanne (including Lausanne and Avenches) were overrun and annexed by Bern (formally ceded in 1564), who added to them (1555) Château d'Oex, as her share of the domains of the debt-laden count of the Gruyère in the division of the spoil she made with Fribourg. Bern in 1526 sent Guillaume Farel, a preacher from Dauphiné, to carry out the Reformation at Aigle, and after 1536 the new religion was imposed by force of arms and the bishop's residence moved to Fribourg (permanently from 1663). Thus the whole land became Protestant, save the district of Échallens. Vaud was ruled very harshly by bailiffs from Bern. In 1588 a plot of some nobles to hand it over to Savoy was crushed, and in 1723 the enthusiastic idealist Davel lost his life in an attempt to raise it to the rank of a canton. Political feeling was therefore much excited by the outbreak of the French Revolution, and a Vaudois, F. C. de la Harpe, an exile and a patriot, persuaded the Directory in Paris to march on Vaud in virtue of alleged rights conferred by a treaty of 1565. The French troops were received enthusiastically, and the "Lemanic republic" was proclaimed (January 1798), succeeded by the short-lived Rhodanic republic, till in March 1798 the canton of Léman was formed as a district of the Helvetic republic. This corresponded precisely with the present canton minus Avenches and Payerne, which were given to the canton of Vaud (set up in 1803). The new canton was thus made up of the Bernese conquests of 1475, 1475–76, 1536 and 1555. The constitutions of 1803 and 1814 favoured the towns and wealthy men, so that an agitation went on for a radical change, which was effected in the constitution of 1831. Originally acting as a mediator, Vaud finally joined the anti-Jesuit movement (especially after the radicals came into power in 1845), opposed the Sonderbund, and accepted the new federal constitution of 1848, of which Druey of Vaud was one of the two drafters. From 1839 to 1846 the canton was distracted by religious struggles, owing to the attempt of the radicals to turn the church into a simple department of state, a struggle which ended in the splitting off (1847) of the "free church." The cantonal feeling in Vaud is very strong, and was the main cause of the failure of the project of revising the federal constitution in 1872, though that of 1874 was accepted. In 1879 Vaud was one of the three cantons which voted (though in vain) against a grant in aid of the St Gotthard railway. In 1882 the radicals obtained a great majority, and in 1885 the constitution of 1861 was revised.

(W. A. B. C.)

VAUDEVILLE, a term now generally given to a musical drama of a light, humorous or comic description interspersed with songs and dances. In English usage "vaudeville" is practically synonymous with what is more generally known as "musical comedy," but in America it is applied also to a music-hall variety entertainment. This modern sense is developed from the French *vaudeville* of the 18th century, a popular form of light dramatic composition, consisting of pantomime, dances, songs and dialogue, written in couplets. It is generally accepted that the word is to be identified with *vau-de-vire*, the name given to the convivial songs of the 15th century. This name originated with a literary association known as the "*Compagnons Gallois*," *i.e.* "boon companions" or "gay comrades" in the valley of the Vire and Virène in Normandy. The most famous of the authors of these songs was Olivier Basselin (*q.v.*). When in the 17th century the term had become applied to topical, satiric verses current in the towns, it was corrupted into its present form, either from *à vau le ville*, or *voix de ville*.

VAUGELAS, CLAUDE FAVRE, SEIGNEUR DE, BARON DE PÉROGES (1595–1650), French grammarian and man of letters, was born at Meximieu, department of Ain, on the 6th of January 1595. He became gentleman-in-waiting to Gaston d'Orléans, and continued faithful to this prince in his disgrace, although his fidelity cost him a pension from the crown on which he was largely dependent. His thorough knowledge of the French language and the correctness of his speech won for him a place among the original academicians. On the representation of his colleagues his pension was restored so that he might have leisure to pursue his admirable *Remarques sur la langue française*

(1647). In this work he maintained that words and expressions were to be judged by the current usage of the best society, of which, as an habitué of the Hôtel de Rambouillet, Vaugelas was a competent judge. He shares with Malherbe the credit of having purified French diction. His book fixed the current usage, and the classical writers of the 17th century regulated their practice by it. Protests against the academical doctrine were not lacking. Scipion Dupleix in his *Liberté de la langue française dans sa pureté* (1651) pleaded for the richer and freer language of the 16th century, and François de la Mothe le Vayer took a similar standpoint in his *Lettres à Gabriel Naudé touchant les Remarques sur la langue française.* Towards the end of his life Vaugelas became tutor to the sons of Thomas Francis of Savoy, prince of Carignan. He died in Paris in February 1650. His translation from Quintus Curtius, *La Vie d'Alexandre* (posthumously published in 1653) deserves notice as an application of the author's own rules.

Bibliography.—See *Remarques sur la langue française*, edited with a key by V. Conrart, and introductory notes by A. Chassang (Paris, 1880). The principles of Vaugelas's judgments are explained in the *Études critiques* (7e série) of M. Brunetière, who regards the name of Vaugelas as a symbol of all that was done in the first half of the 16th century to perfect and purify the French language. See also F. Brunot in the *Histoire de la langue et littérature française* of Petit de Julleville.

VAUGHAN, CHARLES JOHN (1816–1897), English scholar and divine, was educated at Rugby and Cambridge, where he was bracketed senior classic with Lord Lyttelton in 1838. In 1839 he was elected fellow of Trinity College, Cambridge, and for a short time studied law. He took orders, however, in 1841, and became vicar of St Martin's, Leicester. Three years later he was elected headmaster of Harrow. He resigned the headmastership in 1859 and accepted the bishopric of Rochester, but afterwards withdrew his acceptance. In 1880 he was appointed vicar of Doncaster. He was appointed master of the Temple in 1869, and dean of Llandaff in 1879. In 1894 he was elected president of University College, Cardiff, in recognition of the prominent part he took in its foundation. Vaughan was a well-known Broad Churchman, an eloquent preacher and an able writer on theological subjects, his numerous works including lectures, commentaries and sermons; he was joint-author with the Rev. John Llewelyn Davies (b. 1826)—also a well-known Cambridge scholar and Broad Churchman—of a well-known translation of Plato's *Republic.*

VAUGHAN, HENRY (1622–1695), called the "Silurist," English poet and mystic, was born of an ancient Welsh family at Newton St Briget near Scethrog by Usk, Brecknockshire, on the 17th of April 1622. His grandfather, Thomas Vaughan, was the son of Charles Vaughan of Tretower Castle, and had acquired the farm of Newton by marriage. From 1632 to 1638 he and his twin brother Thomas, noticed below, were privately educated by the Rev. Matthew Herbert, rector of Llangattock, to whom they both addressed Latin verses expressing their gratitude. Anthony à Wood, who is the main authority for Vaughan's biography, says that Henry was entered at Jesus College, Oxford, in 1638, but no corroboration of the statement is forthcoming, although Thomas Vaughan's matriculation is entered, nor does Henry Vaughan ever allude to residence at the university.[1] He was sent to London to study law, but turning his attention to medicine, he became a physician, and settled first at Brecon and later at Scethrog to the practice of his art. He was regarded, says Wood, as an "ingenious person, but proud and humorous." It seems likely that he fought on the king's side in the Welsh campaign of 1645, and was present at the battle of Rowton Heath. In 1646 appeared *Poems, with the Tenth Satyre of Juvenal Englished*, by Henry Vaughan, Gent. The poems in this volume are chiefly addressed to "Amoret," and the last is on Priory Grove, the home of the "matchless Orinda," Mrs Katharine Philips. A second volume of secular verse, *Olor Iscanus*, which takes its name from the opening verses addressed to the Isca (Usk), was published by a friend, probably Thomas Vaughan, without the author's consent, in 1651. The book includes three prose translations from Latin versions of Plutarch and Maximus of Tyre, and one in praise of a country life from Guevara. The preface is dated 1647, and the reason for Vaughan's reluctance to print the book is to be sought in the preface to *Silex Scintillans: or Sacred Poems and Pious Ejaculations* (1650). There he says: "The first that with any effectual success attempted a diversion of this foul and overflowing stream (of profane poetry) was the blessed man, Mr George Herbert, whose holy life and verse gained many pious converts, of whom I am the least." He further expresses his debt in "The Match," when he says that his own "fierce, wild blood . . . is still tam'd by those bright fires which thee inflam'd." His debt to Herbert extended to the form of his poetry and sometimes to the actual expressions used in it, and a long list of parallel passages has been adduced. His other works are *The Mount of Olives: or Solitary Devotions*, with a translation, *Man in Glory*, from the Latin of Anselm (1652); *Flores Solitudinis* (1654), consisting of two prose translations from Nierembergius, one from St Eucherius, and a life of Paulinus, bishop of Nola; *Hermetical Physick*, translated from the *Naturae Sanctuarium* of Henricus Nollius; *Thalia Rediviva; The Pass-Times and Diversions of a Country Muse* (1678), which includes some of his brother's poems. Henry Vaughan died at Scethrog on the 23rd of April 1695, and was buried in the churchyard of Llansantffraed.

As a poet Vaughan comes latest in the so-called "metaphysical" school of the 17th century. He is a disciple of Donne, but follows him mainly as he saw him reflected in George Herbert. He analyses his experiences, amatory and sacred, with excessive ingenuity, striking out, every now and then, through his extreme intensity of feeling and his close observation of nature, lines and phrases of marvellous felicity. He is of imagination all compact, and is happiest when he abandons himself most completely to his vision. It is, as Canon H. C. Beeching has said, "undoubtedly the mystical element in Vaughan's writing by which he takes rank as a poet . . . it is easy to see that he has a passion for Nature for her own sake, that he has observed her moods; that indeed the world is to him no less than a veil of the eternal spirit, whose presence may be felt in any, even the smallest part." In this imaginative outlook on Nature he no doubt exercised great influence on Wordsworth, who is known to have possessed a copy of his poems, and it is difficult to avoid seeing in "The Retreat" the germ of the later poet's "Ode on Intimations of Immortality." By this poem, with "The World," mainly because of its magnificent opening stanza, "Beyond the Veil," and "Peace," he is best known to the ordinary reader.

The complete works of Henry Vaughan were edited for the Fuller Worthies Library by Dr A. B. Grosart in 1871. The *Poems of Henry Vaughan, Silurist*, were edited in 1896 by Mr E. K. Chambers, with an introduction by Canon H. C. Beeching, for the Muses' Library.

VAUGHAN, HERBERT (1832–1903), cardinal and archbishop of Westminster, was born at Gloucester on the 15th of April 1832, the eldest son of lieutenant-colonel John Francis Vaughan, head of an old Roman Catholic family, the Vaughans of Courtfield, Herefordshire. His mother, a daughter of John Rolls of The Hendre, Monmouthshire, was intensely religious; and all the daughters of the family entered convents, while six of the eight sons took priest's orders, three of them rising to the episcopate, Roger becoming archbishop of Sydney, and John bishop of Sebastopolis. Herbert spent six years at Stonyhurst, and was then sent to study with the Benedictines at Downside, near Bath, and subsequently at the Jesuit school of Brugelette, Belgium, which was afterwards removed to Paris. In 1851 he went to Rome. After two years of study at the Accademia dei nobili ecclesiastici, where he became a friend and disciple of Manning, he took priest's orders at Lucca in 1854. On his return to England he became for a period

[1] Two poems in the *Eucharistica Oxoniensia* (1641) are signed "H. Vaughan, Jes. Coll.," but are probably by a contemporary of the same name, noticed by Wood. See Mr E. K. Chambers's biographical note in vol. ii. of Vaughan's *Works.*

vice-president of St Edmund's College, Ware, at that time the chief seminary for candidates for the priesthood in the south of England. Since childhood he had been filled with zeal for foreign missions, and he conceived the determination to found a great English missionary college to fit young priests for the work of evangelizing the heathen. With this object he made a great begging expedition to America in 1863, from which he returned with £11,000. St Joseph's Foreign Missionary College, Mill Hill Park, London, was opened in 1869. Vaughan also became proprietor of the *Tablet*, and used its columns vigorously for propagandist purposes. In 1872 he was consecrated bishop of Salford, and in 1892 succeeded Manning as archbishop of Westminster, receiving the cardinal's hat in 1893. Vaughan was a man of very different type from his predecessor; he had none of Manning's intellectual *finesse* or his ardour in social reform, but he was an ecclesiastic of remarkably fine presence and aristocratic leanings, *intransigeant* in theological policy, and in personal character simply devout.

It was his most cherished ambition to see before he died an adequate Roman Catholic cathedral in Westminster, and he laboured untiringly to secure subscriptions, with the result that its foundation stone was laid in 1895, and that when he died, on the 19th of June 1903, the building was so far complete that a Requiem Mass was said there over his body before it was removed to its resting-place at Mill Hill Park.

See the *Life of Cardinal Vaughan*, by J. G. Snead Cox (2 vols., London, 1910).

VAUGHAN, THOMAS (1622–1666), English alchemist and mystic, was the younger twin brother of Henry Vaughan, the "Silurist." He matriculated from Jesus College, Oxford, in 1638, took his B.A. degree in 1642, and became fellow of his college. He remained for some years at Oxford, but also held the living of his native parish of Llansantfread from 1640 till 1649, when he was ejected, under the Act for the Propagation of the Gospel in Wales, upon charges of drunkenness, immorality and bearing arms for the king. Subsequently he lived at his brother's farm of Newton and in various parts of London, and studied alchemy and kindred subjects. He married in 1651 and lost his wife in 1658. After the Restoration he found a patron in Sir Robert Murray, with whom he fled from London to Oxford during the plague of 1665. He appears to have had some employment of state, but he continued his favourite studies and actually died of the fumes of mercury at the house of Samuel Kem at Albury on the 27th of February 1666. Vaughan regarded himself as a philosopher of nature, and although he certainly sought the universal solvent, his published writings deal rather with magic and mysticism than with technical alchemy. They also contain much controversy with Henry More the Platonist. Vaughan was called a Rosicrucian, but denied the imputation. He wrote or translated *Anthroposophia Theomagica* (1650); *Anima Magica Abscondita* (1650); *Magia Adamica* and *Coelum Terrae* (1650); *The Man-Mouse taken in a Trap* (1650); *The Second Wash; or the Moor Scoured once more* (1651); *Lumen de Lumine* and *Aphorisimi Magici Eugeniani* (1651); *The Fame and Confession of the Fraternity of R.C.* (1652); *Aula Lucis* (1652); *Euphrates* (1655); *Nollius' Chymist's Key* (1657); *A Brief Natural History* (1669). Most of these pamphlets appeared under the pseudonym of Eugenius Philalethes. Vaughan was probably, although it is by no means certain, *not* the famous adept known as Eirenaeus Philalethes, who was alleged to have found the philosopher's stone in America, and to whom the *Introitus Apertus in Occlusum Regis Palatium* (1667) and other writings are ascribed. In 1896 Vaughan was the subject of an amazing mystification in the *Mémoires d'une ex-Palladiste*. These formed part of certain alleged revelations as to the practice of devil-worship by the initiates of freemasonry. The author, whose name was given as Diana Vaughan, claimed to be a descendant of Thomas and to possess family papers which showed amongst other marvels that he had made a pact with Lucifer, and had helped to found freemasonry as a Satanic society. The inventors of the hoax, which took in many eminent Catholic ecclesiastics, were some unscrupulous Paris journalists.

The Magical Writings of Thomas Vaughan were edited by Mr A. E. Waite in 1888. His miscellaneous Latin and English verses are included in vol. ii. of Dr A. B. Grosart's Fuller Worthies Library edition of the *Works* of Henry Vaughan (1871). A manuscript book of his, with alchemical and autobiographical jottings made between 1658 and 1662, forms *Brit. Mus. Sloane MS.* 1741. Biographical data are in Mr E. K. Chambers's Muses Library edition of the *Poems* of Henry Vaughan (1896), together with an account and criticism of the *Mémoires d'une ex-Palladiste*. These fabrications were also discussed by Mr A. E. Waite, *Devil-Worship in France* (1896), and finally exposed by M. Gaston Méry, *La Vérité sur Diana Vaughan*. (E. K. C.)

VAUGHAN, WILLIAM (1577–1641), English author and colonial pioneer, son of Walter Vaughan (d. 1598), was born at Golden Grove, Carmarthenshire, his father's estate, in 1577. He was descended from an ancient prince of Powys. His brother, John Vaughan (1572–1634), became 1st earl of Carbery; and another brother, General Sir Henry or Harry Vaughan (1587–1659), was a well-known royalist leader. William was educated at Jesus College, Oxford, and took the degree of LL.D. at Vienna. In 1616 he bought a grant of land in the south coast of Newfoundland, to which he sent two batches of settlers. In 1622 he visited the settlement, which he called Cambriol, and returned to England in 1625. Vaughan apparently paid another visit to his colony, but his plans for its prosperity were foiled by the severe winters. He died at his house of Torcoed, Carmarthenshire, in August 1641.

His chief work is *The Golden Grove* (1600), a general guide to morals, politics and literature, in which the manners of the time are severely criticized, plays being denounced as folly and wickedness. The section in praise of poetry borrows much from earlier writers on the subject. *The Golden Fleece . . . transported from Cambriol Colchis . . . by Orpheus jun., alias Will Vaughan*, which contains information about Newfoundland, is the most interesting of his other works.

VAULT[1] (Fr. *voute*, Ital. *volta*, Ger. *Gewölbe*), in architecture, the term given to the covering over of a space with stone or brick in arched form, the component parts of which exert a thrust and necessitate a counter resistance. In the case of vaults built under the level of the ground, the latter gave all that was required, but, when raised aloft, various expedients had to be employed, such as great thickness of walls in the case of barrel or continuous vaults, and cross walls or buttresses when intersecting vaults were employed. The simplest kind of vault is that known as the barrel, wagon or tunnel vault, which is generally semicircular in section, and may be regarded as a continuous arch, the length of which is in excess of its diameter; like the arch (*q.v.*), the same provision is required as regards its temporary support whilst the voussoirs constituting one of its rings are being placed in position, for until the upper voussoir, or keystone, is introduced it is not self-supporting. At the present day, when timber of all kinds is easily procurable, this temporary support is given by centring, consisting of a framed truss with semicircular or segmental head, which carries the voussoirs until the ring of the whole arch is completed and is then, with a barrel vault, shifted on to support other rings; in early times, and particularly in Chaldaea and Egypt, where timber was scarce, other means of support had to be contrived, and it would seem that it was only in Roman times that centring was regularly employed.

The earliest example known of a vault is that found under the Chaldaean ziggurat at Nippur in Babylonia, ascribed to about 4000 B.C., which was built of burnt bricks cemented with clay mortar. The earliest tunnel vaults in Egypt are those at Requaqnah and Denderah, *c.* 3500 B.C.; these were built in unburnt brick in three rings over passages descending to tombs: in these cases, as the span of the vault was only 6 ft., the bricks constituting the voussoirs were laid flatwise, and adhered sufficiently to those behind to enable the ring to be completed without other support; in the granaries built by Ramessu II., still in part existing behind the Ramesseum, at Thebes, the span was 12 ft., and another system was employed; the lower part of

[1] For the form of safe so called see SAFES.

the arch was built in horizontal courses, up to about one-third of the height, and the rings above were inclined back at a slight angle, so that the bricks of each ring, laid flatwise, adhered till the ring was completed, no centring of any kind being required; the vault thus formed was elliptic in section, arising from the method of its construction. A similar system of construction was employed for the vault over the great hall at Ctesiphon, where the material employed was burnt bricks or tiles of great dimensions, cemented with mortar; but the span was close upon 83 ft., and the thickness of the vault was nearly 5 ft. at the top, there being four rings of brickwork. It is probable that the great vaults of the Assyrian palaces were constructed in the same way, but with unburnt bricks dried only in the sun: one of the drains discovered by Layard at Nimrud was built in rings sloping backwards. From the fact that each Assyrian monarch on his accession to the throne commenced his reign by the erection of a palace, it is probable that, owing to the ephemeral construction of these great vaults, half a century was the term of their existence. This may also account for the fact that no domed structures exist of the type shown in one of the bas reliefs from Nimrud (fig. 1); the tradition of their

FIG. 1.

erection, however, would seem to have been handed down to their successors in Mesopotamia, viz. to the Sassanians, who in their palaces at Serbistan and Firuzabad built domes of similar form to those shown in the Nimrud sculptures, the chief difference being that, constructed in rubble stone and cemented with mortar, they still exist, though probably abandoned on the Mahommedan invasion in the 7th century.

In all the instances above quoted in Chaldaea and Egypt the bricks, whether burnt or sun-dried, were of the description to which the term "tile" would now be given; the dimensions varied from 18 or 20 in. to 10 in., being generally square and about 4 to 2 in. thick, and they were not shaped as voussoirs, the connecting medium being thicker at the top than at the bottom. The earliest Egyptian examples of regular voussoirs in stone belong to the XXVIth Dynasty (*c.* 650 B.C.) in the additions made then to the temple of Medinet-Abou, and here it is probable that centring of some kind was provided, as the vaults are built in rings, so that the same centring could be shifted on after the completion of each ring. The earliest example of regularly shaped voussoirs, and of about the same date, is found in the *cloaca* at Graviscae in Etruria, with a span of about 14 ft., the voussoirs of which are from 5 to 6 ft. long. The *cloaca maxima* in Rome, built by Tarquin (603 B.C.) to drain the marshy ground between the Palatine and the Capitoline Hills, was according to Commendatore Boni vaulted over in the 1st century B.C., the vault being over 800 ft. long, 10 ft. in span, with three concentric rings of voussoirs.

So far, all the vaults mentioned have been barrel vaults, which, when not built underground, required continuous walls of great thickness to resist their thrust; the earliest example of the next variety, the intersecting barrel vault, is said to be over a small hall at Pergamum, in Asia Minor, but its first employment over halls of great dimensions is due to the Romans. When two semicircular barrel vaults of the same diameter cross one another (fig. 2) their intersection (a true ellipse) is known as a groin, down which the thrust of the vault is carried to the cross walls; if a series of two or more barrel vaults intersect one another, the weight is carried on to the piers at their intersection and the thrust is transmitted to the outer cross walls; thus in the Roman reservoir at Baiae, known as the *piscina mirabilis*, a series of five aisles with semicircular barrel vaults are intersected by twelve cross aisles, the vaults being carried on 48 piers and thick external walls. The width of these aisles being only about 13 ft. there was no great difficulty in the construction of these vaults, but in the Roman Thermae the tepidarium had a span of 80 ft., more than twice that of an English cathedral, so that its construction both from the statical and economical point of view was of the greatest importance. The researches of M. Choisy (*L'Art de bâtir chez les Romains*), based on a minute examination of those portions of the vaults which still remain *in situ*, have shown that, on a comparatively slight centring, consisting of trusses placed about 10 ft. apart and covered with planks laid from truss to truss, were laid—to begin with—two layers of the Roman brick (measuring nearly 2 ft. square and 2 in. thick); on these and on the trusses transverse rings of brick were built with longitudinal ties at intervals; on the brick layers and embedding the rings and cross ties concrete was thrown in horizontal layers, the haunches being filled in solid, and the surface sloped on either side and covered over with a tile roof of low pitch laid direct on the concrete. The rings relieved the centring from the weight imposed, and the two layers of bricks carried the concrete till it had set. As the walls carrying these vaults were also built in concrete with occasional bond courses of brick, the whole structure was homogeneous. One of the important ingredients of the mortar was a volcanic deposit found near Rome, known as pozzolana, which, when the concrete had set, not only made the concrete as solid as the rock itself, but to a certain extent neutralized the thrust of the vaults, which formed shells equivalent to that of a metal lid; the Romans, however, do not seem to have recognized the extraordinary value of this pozzolana mixture, for they otherwise provided amply for the counteracting of any thrust which might exist by the erection of cross walls and buttresses. In the tepidaria of the Thermae and in the basilica of Constantine, in order to bring the thrust well within the walls, the main barrel vault of the hall was brought forward on each side and rested on detached columns, which constituted the principal architectural decoration. In cases where the cross vaults intersecting were not of the same span as those of the main vault, the arches were either stilted so that their soffits might be of the same height, or they formed smaller intersections in the lower part of the vault; in both of these cases, however, the intersections or groins were twisted, for which it was very difficult to form a centring, and, moreover, they were of disagreeable effect: though every attempt was made to mask this in the decoration of the vault by panels and reliefs modelled in stucco.

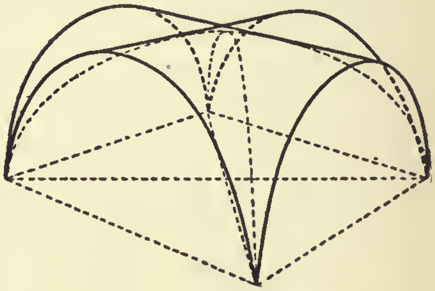

FIG. 2.

The widest hall vaulted by the Romans was that of the throne room in the palace of Diocletian on the Palatine Hill, and this had the enormous span of 100 ft., its thrust being counteracted by other halls on either side with buttresses outside. In provincial towns and in other parts of the Roman Empire, where the material pozzolana was not procurable, the Romans had to trust to their mortar as a cementing medium, but this, though excellent of its kind, was not of sufficient cohesive strength to allow of the erection of vaults of more than about 40 ft. span, which were generally built in rubble masonry. There still exist in Asia Minor and Syria some vaulted halls, generally attached to thermae, which are carried on walls of great thickness. There were many varieties of the Roman vault, whether continuous or intersected, such as those employed over the corridors on the Colosseum and the theatre of Marcellus, but in these cases the springing of the vault was above the summit of the arches of the main front, so that there was no intersection; on the other hand, over the corridors were either elliptical or semicircular, or over the staircases rising vaults, all of which were more difficult to construct; there were also numerous solutions of vault over circular halls, of which that of the Pantheon was the most important example, having a diameter of 142 ft., and over the hemicycles, which were sometimes of great size; that known as Canopus in Hadrian's villa at Tivoli had a diameter of 75 ft., and was vaulted over with a series of ribs, between which were alternating rampant flat and semicircular webs and cells; in the same villa and in Rome were octagonal halls with various other combinations of vault. Another type of vault not yet referred to is that of the Tabularium arcade where the cloister vault was employed. Fig. 3 compared with fig. 2 will show the difference; in the former the angles of intersection are inset, and in the latter they are groins with projecting angles at the base, which die away at the summit.

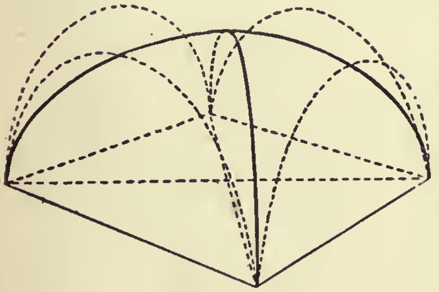

FIG. 3.

The vault of the basilica, commenced by Diocletian and completed by Constantine, was the last great work carried out by the Romans, and two centuries pass before the next important development is found in the church of Sta Sophia at Constantinople. It is probable that the realization of the great advance in the science of vaulting shown in this church owed something to the eastern tradition of dome vaulting seen in the Assyrian domes, which are known to us only by the representations in the bas-relief from Nimrud (fig. 1), because in the great water cisterns in Constantinople, known as the Yeri Batan Serai (the underground palace) and Bin bir-derek (cistern with a thousand and one columns), both built by Constantine, we find the intersecting groin vaults of the Romans already replaced by small cupolas or domes. These domes, however, are of small dimensions when compared with that projected and carried out by Justinian in Sta Sophia. Previous to this the greatest dome was that of the Pantheon at Rome, but this was carried on an immense wall 20 ft. thick, and with the exception of small niches or recesses in the thickness of the wall could not be extended, so that Justinian apparently instructed his architect to provide an immense hemicycle or apse at the eastern end, a similar apse at the western end, and great arches on either side, the walls under which would be pierced with windows.

The diagram (fig. 4) shows the outlines of the solution of the problem. If a hemispherical dome is cut by four vertical planes, the intersection gives four semicircular arches; if cut in addition by a horizontal plane tangent to the top of these arches, it describes a circle; that portion of the sphere which is below this circle and between the arches, forming a spherical spandril, is the pendentive (fig. 5), and its radius is equal to the diagonal of the square on which the four arches rest. Having obtained a circle for the base of the dome, it is not necessary that the upper portion of the dome should

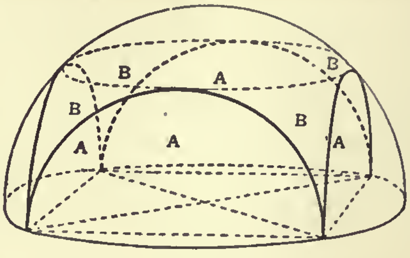

FIG. 4.

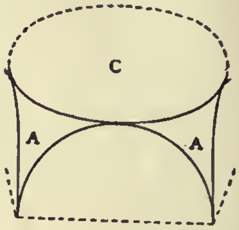

FIG. 5.—AA, pendentive.

spring from the same level as the arches, or that its domical surface should be a continuation of that of the pendentive. The first and second dome of Sta Sophia apparently fell down, so that Justinian determined to raise it, possibly to give greater lightness to the structure, but mainly in order to obtain increased light for the interior of the church. This was effected by piercing it with forty windows—the effect of which was of an extraordinary nature, as the light streaming through these windows gave to the dome the appearance of being suspended in the air. The pendentive which carried the dome rested on four great arches, the thrust of those crossing the church being counteracted by immense buttresses which traversed the aisles, and the other two partly by smaller arches in the apse, the thrust being carried to the outer walls, and to a certain extent by the side walls which were built under the arches. From the description given by Procopius we gather that the centring employed for the great arches consisted of a wall erected to support them during their erection. The construction of the pendentives is not known, but it is surmised that to the top of the pendentives they were built in horizontal courses of brick, projecting one over the other, the projecting angles being cut off afterwards and covered with stucco in which the mosaics were embedded; this was the method employed in the erection of the Perigordian domes, to which we shall return; these, however, were of less diameter than those of Sta Sophia, being only about 40 to 60 ft. instead of 107 ft. The apotheosis of Byzantine architecture, in fact, was reached in Sta Sophia, for although it formed the model on which all subsequent Byzantine churches were based, so far as their plan was concerned, no domes approaching the former in dimensions were even attempted. The principal difference in some later examples is that which took place in the form of the pendentive on which the dome was carried. Instead of the spherical spandril of Sta Sophia, large niches were formed in the angles, as in the mosque of Damascus, which was built by Byzantine workmen for the Sherif al Walid in A.D. 705; these gave an octagonal base on which the hemispherical dome rested (fig. 6); or again, as in the Sassanian palaces of Serbistan and Firuzabad of the 4th and 5th century of our era, when a series of concentric arch rings, projecting one in front of the other, were built, giving also an octagonal base; each of these pendentives is known as a squinch.

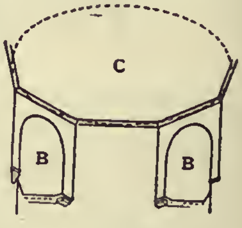

FIG. 6.—BB, niche or squinch pendentive.

There is one other remarkable vault, also built by Justinian, in the church of S. Sergius and Bacchus in Constantinople. The central area of this church was octagonal on plan, and the dome is divided into sixteen compartments; of these eight consist of broad flat bands rising from the centre of each of the walls, and the alternate eight are concave cells over the angles of the octagon, which externally and internally give to the roof the appearance of an umbrella.

Although the dome constitutes the principal characteristic of the Byzantine church, throughout Asia Minor are numerous examples in which the naves are vaulted with the semicircular barrel vault, and this is the type of vault found throughout the south of France in the 11th and 12th centuries, the only change being the occasional substitution of the pointed barrel vault, adopted not only on account of its exerting a less thrust, but because, as pointed out by Fergusson (vol. ii. p. 46), the roofing tiles were laid directly on the vault and a less amount of filling in at the top was required. The continuous thrust of the barrel vault in these cases was met either by semicircular or pointed barrel vaults on the aisles, which had only half the span of the nave; of this there is an interesting example in the chapel of St John in the Tower of London—and sometimes by half-barrel vaults. The great thickness of the walls, however, required in such constructions would seem to have led to another solution of the problem of roofing over churches with incombustible material, viz. that which is found throughout Perigord and La Charente, where a series of domes carried on pendentives covered over the nave, the chief peculiarities of these domes being the fact that the arches carrying them form part of the pendentives, which are all built in horizontal courses.

The intersecting and groined vault of the Romans was employed in the early Christian churches in Rome, but only over the aisles, which were comparatively of small span, but in these there was a tendency to raise the centres of these vaults, which became slightly domical; in all these cases centring was employed.

Reference has been made to the twisting of the groins in Roman work, where the intersecting barrel vaults were not of the same diameter; their construction must at all times have been somewhat difficult, but where the barrel vaulting was carried round over the choir aisle and was intersected, as in St Bartholomew's, Smithfield, by semicones, instead of cylinders, it became worse and the groins more complicated; this would seem to have led to a change of system, and to the introduction of a new feature, which completely revolutionized the construction of the vault. Hitherto the intersecting features were geometrical surfaces, of which the diagonal groins were the intersections, elliptical in form, generally weak in construction and often twisting (Plate I. fig. 13). The medieval builder reversed the process, and set up the diagonal ribs first, which were utilized as permanent centres, and on these he carried his vault or web, which henceforward took its shape from the ribs. Instead of the elliptical curve which was given by the intersection of two semicircular barrel vaults, or cylinders, he employed the semicircular arch for the diagonal ribs; this, however, raised the centre of the square bay vaulted above the level of the transverse arches and of the wall ribs, and thus gave the appearance of a dome to the vault, such as may be seen in the nave of Sant' Ambrogio, Milan. To meet this, at first the transverse and wall ribs were stilted, or the upper part of their arches was raised, as in the Abbaye-aux-Hommes at Caen, and the abbey of Lessay, in Normandy. The problem was ultimately solved by the introduction of the pointed arch for the transverse and wall ribs—the pointed arch had long been known and employed, on account of its much greater strength and of the less thrust it exerted on the walls. When employed for the ribs of a vault, however narrow the span might be, by adopting a pointed arch, its summit could be made to range in height with the diagonal rib; and, moreover, when utilized for the ribs of the annular vault, as in the aisle round the apsidal termination of the choir, it was not necessary that the half ribs on the outer side should be in the same plane as those of the inner side; for when the opposite ribs met in the centre of the annular vault, the thrust was equally transmitted from one to the other, and being already a broken arch the change of its direction was not noticeable.

The first introduction of the pointed arch rib would seem to have taken place in the choir aisles of the abbey of St Denis, near Paris, built by the Abbé Suger in 1135, and it was in the church at Vezelay (1140) that it was extended to the square bay of the porch. Before entering into the question of the web or stone shell of the vault carried on the ribs, the earlier development of the great vaults which were thrown over the naves of a cathedral, or church, before the introduction of the pointed arch rib, shall here be noted. As has been pointed out, the aisles had already in the early Christian churches been covered over with groined vaults, the only advance made in the later developments being the introduction of transverse ribs[1] dividing the bays into square compartments; but when in the 12th century the first attempts were made to vault over the naves, another difficulty presented itself, because the latter were twice the width of the aisles, so that it became necessary to include two bays of the aisles to form one square bay in the nave. This was an immense space to vault over, and, moreover, it followed that every alternate pier served no purpose, so far as the support of the nave vault was concerned, and this would seem to have suggested an alternative, viz. to provide a supplementary rib across the church and between the transverse ribs. This resulted in what is known as a sexpartite, or six-celled vault, of which one of the earliest examples is found in the Abbaye-aux-Hommes (S. Étienne) at Caen. This church, built by William the Conqueror, was originally constructed to carry a timber roof only, but nearly a century later the upper part of the nave walls were partly rebuilt, in order that it might be covered with a vault. The immense size, however, of the square vault over the nave necessitated some additional support, so that an intermediate rib was thrown across the church, dividing the square compartment into six cells, and called the sexpartite vault (fig. 7);

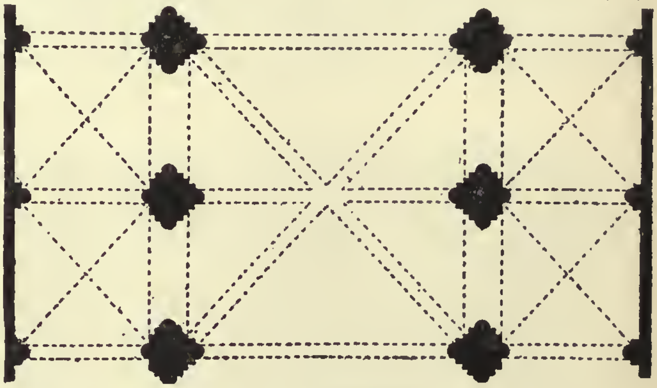

Fig. 7.—Sexpartite.

this was adopted in the cathedrals of Sens (1170), Laon (1195), Noyon (1190), Paris (1223–35), and Bourges (1250). The intermediate rib, however, had the disadvantage of partially obscuring one side of the clerestory windows, and it threw unequal weights on the alternate piers, so that in the cathedral of Soissons (1205) a quadripartite (fig. 8) or

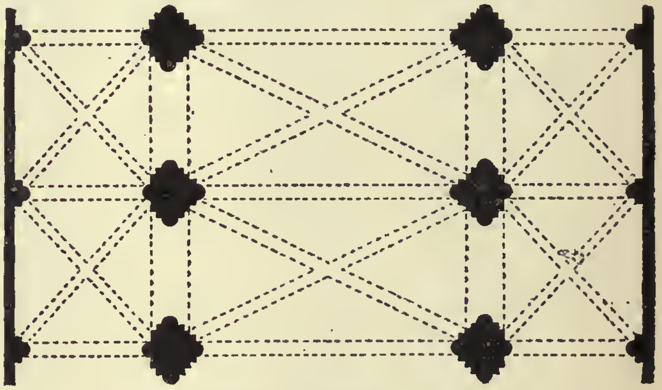

Fig. 8.—Quadripartite.

four-celled vault was introduced, the width of each bay being half the span of the nave, and corresponding therefore with the aisle piers. To this there are some exceptions, in Sant' Ambrogio, Milan, and San Michele, Pavia (the original vault), and in the cathedrals of Spires, Mainz and Worms, where the quadripartite vaults are nearly square, the intermediate piers of the aisles being of much smaller dimensions. In England sexpartite vaults exist at Canterbury (1175) (set out by William of Sens), Rochester (1200), Lincoln (1215), Durham (east transept), and St Faith's chapel, Westminster Abbey.

In the earlier stage of rib vaulting, the arched ribs consisted of independent or separate voussoirs down to the springing; the difficulty, however, of working the ribs separately led to two other important changes: (1) the lower part of the transverse diagonal

[1] Transverse ribs under the vaulting surfaces had been employed from very early times by the Romans, and utilized as permanent stone centrings for their vaults; perhaps the earliest examples are those in the corridor of the Tabularium in Rome, which is divided into square bays, each vaulted with a cloister dome. Transverse ribs are also found in the Roman Piscinae and in the Nymphaeum at Nîmes; they were not introduced by the Romanesque masons till the 11th century.

and wall ribs were all worked out of one stone; and (2) the lower courses were all made horizontal, constituting what is known as the tas-de-charge (*q.v.*) or solid springer. Fig. 9 is a diagram made by Professor Willis taken from the south transept of Westminster Abbey. The horizontal courses rise to N. or about half the height of the vault, but the ribs are freed from one another from the point M. The tas-de-charge, or solid springer, had two advantages: (1) it enabled the stone courses to run straight through the wall, so as to bond the whole together much better; and (2) it lessened the span of the vault, which then required a centring of smaller dimensions. As soon as the ribs were completed, the web or stone shell of the vault was laid on them. In some English work, as may be seen in fig. 9, each course of stone was of uniform height from one side to the other; but, as the diagonal rib was longer than either the transverse or wall rib, the courses dipped towards the former, and at the apex of the vault were cut to fit one another. At an early period, in consequence of the great span of the vault and the very slight rise or curvature of the web, it was thought better to simplify the construction of the web by introducing intermediate ribs between the wall rib and the diagonal rib and between the diagonal and the transverse ribs; and in order to meet the thrust of these intermediate ribs a ridge rib was required, and the prolongation of this rib to the wall rib hid the junction of the web at the summit, which was not always very sightly, and constituted the ridge rib. In France, on the other hand, the web courses were always laid horizontally, and they are therefore of unequal height, increasing towards the diagonal rib. Each course also was given a slight rise in the centre, so as to increase its strength; this enabled the French masons to dispense with the intermediate rib, which was not introduced by them till the 15th century, and then more as a decorative than a constructive feature, as the domical form given to the French web rendered unnecessary the ridge rib, which, with some few exceptions, exists only in England. In both English and French vaulting centring was rarely required for the building of the web, a template (Fr. *cerce*) being employed to support the stones of each ring until it was complete. In Italy, Germany and Spain the French method of building the web was adopted, with horizontal courses and a domical form. Sometimes, in the case of comparatively narrow compartments, and more especially in clerestories, the wall rib was stilted, and this caused a peculiar twisting of the web, as may be seen in fig. 9, where the springing of the wall rib is at K: to these twisted surfaces the term "ploughshare vaulting" is given.

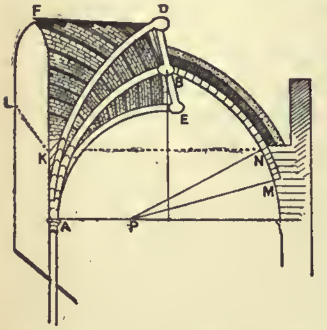

Fig. 9.—AB, springing of transverse and diagonal ribs; P, centre of the same; DE, longitudinal ridge rib; DF, intersection of webs; M, top of solid springer; KN, starting level of web; LK, springing of wall rib; EBD, bosses at intersection of ribs.

One of the earliest examples of the introduction of the intermediate rib is found in the nave of Lincoln Cathedral, and there the ridge rib is not carried to the wall rib. It was soon found, however, that the construction of the web was much facilitated by additional ribs, and consequently there was a tendency to increase their number, so that in the nave of Exeter Cathedral three intermediate ribs were provided between the wall rib and the diagonal rib. In order to mask the junction of the various ribs, their intersections were ornamented with richly carved bosses, and this practice increased on the introduction of another short rib, known as the lierne, a term in France given to the ridge rib. Lierne ribs in English vaults are short ribs crossing between the main ribs, and were employed chiefly as decorative features, as, for instance, in the stellar vault (see Plate I. fig. 16), one of the best examples of which exists in the vault of the oriel window of Crosby Hall, London. The tendency to increase the number of ribs led to singular results in some cases, as in the choir of Gloucester (see Plate II. fig. 17), where the ordinary diagonal ribs become mere ornamental mouldings on the surface of an intersected pointed barrel vault, and again in the cloisters, where the introduction of the fan vault, forming a concave-sided conoid, returned to the principles of the Roman geometrical vault. This is further shown in the construction of these fan vaults, for although in the earliest examples each of the ribs above the tas-de-charge was an independent feature, eventually it was found easier to carve them and the web out of the solid stone, so that the rib and web were purely decorative and had no constructional or independent functions.

The fan vault would seem to have owed its origin to the employment of centrings of one curve for all the ribs, instead of having separate centrings for the transverse, diagonal wall and intermediate ribs; it was facilitated also by the introduction of the four-centred arch, because the lower portion of the arch formed part of the fan, or conoid, and the upper part could be extended at pleasure with a greater radius across the vault. The simplest version is that found in the cloisters of Gloucester Cathedral, where the fans meet one another at the summit, so that there are only small compartments between the fans to be filled up. In later examples, as in King's College chapel, Cambridge (see Plate II. fig. 18), on account of the great dimensions of the vault, it was found necessary to introduce transverse ribs, which were required to give greater strength. Similar transverse ribs are found in Henry VII.'s chapel (see Plate II. fig. 19) and in the divinity schools at Oxford, where a new development presented itself. One of the defects of the fan vault at Gloucester is the appearance it gives of being half sunk in the wall; to remedy this, in the two buildings just quoted, the complete conoid is detached and treated as a pendant.

One of the most interesting examples of the fan vault is that over the staircase leading to the hall of Christ Church, Oxford, and here the complete conoid is displayed in its centre carried on a central column. This vault, not built until 1640, is an exceptional example of the long continuance of traditional workmanship, probably in Oxford transmitted in consequence of the late vaulting of the entrance gateways to the colleges. Fan vaulting is peculiar to England, the only example approaching it in France being the pendant of the Lady chapel at Caudebec, in Normandy. In France, Germany and Spain the multiplication of ribs in the 15th century led to decorative vaults of various kinds, but with some singular modifications. Thus in Germany, recognizing that the rib was no longer a necessary constructive feature, they cut it off abruptly, leaving a stump only; in France, on the other hand, they gave still more importance to the rib, by making it of greater depth, piercing it with tracery and hanging pendants from it, and the web became a horizontal stone paving laid on the top of these decorated vertical webs. This is the characteristic of the great Renaissance work in France and Spain; but it soon gave way to Italian influence, when the construction of vaults reverted to the geometrical surfaces of the Romans, without, however, always that economy in centring to which they had attached so much importance, and more especially in small structures. In large vaults, where it constituted an important element in expense, the chief boast of some of the most eminent architects has been that centring was dispensed with, as in the case of the dome at Florence, built by Brunelleschi, and Ferguson cites as an example the great dome of the church at

FIG. 19.—FAN VAULTING. Henry VII. Chapel, Westminster.

Mousta in Malta, erected in the first half of the 19th century, which was built entirely without centring of any kind. Fig. 10 is a plan and section of the vault of Henry VII.'s chapel and fig. 11 a perspective view, in which it will be seen that the transverse rib thrown across the chapel carries the pendant, the weight of the latter probably preventing a rise in the haunches.

There are two other ribbed vaults in India which form no part of the development of European vaults, but are too remarkable to be passed over; one carries the central dome of the Jumma Musjid at Bijapur (A.D. 1559), and the other is the tomb of Mahommed (A.D. 1626–1660) in the same town. The vault of the latter was constructed over a hall 135 ft. square, to carry a hemispherical dome. The ribs, instead of being carried across the angles only, thus giving an octagonal base for the dome, are carried across to the further pier of the octagon (fig. 12) and consequently intersect one another, reducing the central opening to 97 ft. in diameter, and, by the weight of the masonry they carry, serving as counterpoise to the thrust of the dome, which is set back so as to leave a passage about 12 ft. wide round the interior. The internal diameter of the dome is 124 ft., its height 175 ft. and the ribs struck from four centres have their springing 57 ft. from the floor of the hall. The Jumma Musjid dome was of smaller dimensions, on a square of 70 ft. with a diameter of 57 ft., and was carried on piers only instead of immensely thick walls as in the tomb; but any thrust which might exist was counteracted by its transmission across aisles to the outer wall.

VAUQUELIN, LOUIS NICOLAS (1763–1829), French chemist, was born at Saint-André-d'Hebertot in Normandy on the 16th of May 1763. His first acquaintance with chemistry was gained as laboratory boy to an apothecary in Rouen (1777–1779), and after various vicissitudes he obtained an introduction to A. F. Fourcroy, in whose laboratory he was an assistant from 1783–1791. At first his work appeared as that of his master and patron, then in their joint-names; but in 1790 he began to publish on his own authority, and between that year and 1833 his name is associated with 376 papers. Most of these were simple records of patient and laborious analytical operations, and it is perhaps surprising that among all the substances he analysed he only detected two new elements—beryllium (1798) in beryl and chromium (1797) in a red lead ore from Siberia. Either together or successively he held the offices of inspector of mines, professor at the School of Mines and at the Polytechnic School, assayer of gold and silver articles, professor of chemistry in the *Collège de France* and at the *Jardin des Plantes*, member of the Council of Industry and Commerce, commissioner on the pharmacy laws, and finally professor of chemistry to the Medical Faculty, to which he succeeded on Fourcroy's death in 1809. His lectures, which were supplemented with practical laboratory teaching, were attended by many chemists who subsequently attained distinction. He died at his birthplace on the 14th of November 1829.

VAUQUELIN DE LA FRESNAYE, JEAN (1536–1608), French poet, was born at the château of La Fresnaye, near Falaise in Normandy, in 1536. He studied the humanities at Paris and law at Poitiers and Bourges. He fought in the civil wars under Marshal Matignon and was wounded at the siege of Saint-Lô (1574). Most of his life was spent at Caen, where he was president, and he died there in 1608. La Fresnaye was a disciple of Ronsard, but, while praising the reforms of the Pléiade, he laid stress on the continuity of French literary history. He was a student of the trouvères and the old chroniclers, and desired to see French poetry set on a national basis. These views he expounded in an *Art poëtique*, begun at the desire of Henry III. in 1574, but not published until 1605.

His *Foresteries* appeared in 1555; his *Diverses poésies*, including the *Art poëtique*, the *Satyres françoises*, addressed to various distinguished contemporaries, and the *Idylles*, with some epigrams and sonnets, appeared in 1605. Among his political writings may be noted *Pour la monarchie du royaume contre la division* (1569).

The *Art poëtique* was edited by G. Pellissier in 1885. It is summarized for English readers in vol. ii. of Mr George Saintsbury's *History of Criticism*. A notice of the poet by J. Travers is prefixed to an edition of the *Œuvres diverses* (Caen, 1872).

VAUVENARGUES, LUC DE CLAPIERS, Marquis de (1715–1747), French moralist and miscellaneous writer, was born at Aix in Provence on the 6th of August 1715. His family was poor though noble; he was educated at the collège of Aix, where he learned little—neither Latin nor Greek—but by means of a translation acquired a great admiration for Plutarch. He entered the army as sub-lieutenant in the king's regiment, and served for more than ten years, taking part in the Italian campaign of Marshal Villars in 1733, and in the disastrous expedition to Bohemia in support of Frederick the Great's designs on Silesia, in which the French were abandoned by their ally. Vauvenargues took part in Marshal Belle-Isle's winter retreat from Prague. On this occasion his legs were frozen, and though he spent a long time in hospital at Nancy he never completely recovered. He was present at the battle of Dettingen, and on his return to France was garrisoned at Arras. His military career was now at an end. He had long been desired by the marquis of Mirabeau, author of *L'Ami des hommes*, and father of the statesman, to turn to literature, but poverty prevented him from going to Paris as his friend wished. He wished to enter the diplomatic service, and made applications to the ministers and to the king himself. These efforts were unsuccessful, but Vauvenargues was on the point of securing his appointment through the intervention of Voltaire when an attack of smallpox completed the ruin of his health and rendered diplomatic employment out of the question. Voltaire then asked him to submit to him his ideas of the difference between Racine and Corneille. The acquaintance thus begun ripened into real and lasting friendship. Vauvenargues removed to Paris in 1745, and lived there in the closest retirement, seeing but few friends, of whom Marmontel and Voltaire were the chief. Among his correspondents was the archaeologist Fauris de Saint-Vincens. Vauvenargues published in 1746 an *Introduction à la connaissance de l'esprit humain*, with certain *Réflexions* and *Maximes* appended. He died in Paris on the 28th of May 1747.

The bulk of Vauvenargues's work is very small, but its interest is very considerable. In the *Introduction*, in the *Réflexions* and in the minor fragments, it consists, in fact, of detached and somewhat desultory thoughts on questions of moral philosophy and of literary criticism. Sainte-Beuve has mildly said that as a literary critic Vauvenargues "shows inexperience." His literary criticism is indeed limited to a repetition in crude form of the stock ideas of his time. Thus he exaggerates immensely the value of Racine and Boileau, but depreciates Corneille and even Molière. As a writer he stands far higher. His style is indeed, according to strict academic judgment, somewhat incorrect, and his few excursions into rhetoric have the artificial and affected character which mars so much 18th-century work. His strength, however, is not really in any way that of a man of letters, but that of a moralist. He did not adopt the complete *philosophe* attitude; in his letters, at any rate, he poses as "neutral" between the religious and the anti-religious school. In some of his maxims about politics there is also traceable the hollow and confused jargon about tyrants and liberty which did so much to bring about the struggles of the Revolution. It is in morals proper, in the discussion and application of general principles of conduct, that Vauvenargues shines. He is not an exact psychologist, much less a rigorous metaphysician. His terminology is popular and loose, and he hardly attempts the co-ordination of his ideas into any system. His real strength is in a department which the French have always cultivated with greater success than any other modern people—the expression in more or less epigrammatic language of the results of acute observation of human conduct and motives, for which he had found ample leisure in his campaigns. The chief distinction between Vauvenargues and his great predecessor La Rochefoucauld is that Vauvenargues, unlike La Rochefoucauld, thinks nobly of man, and is altogether inclined rather to the Stoic than to the Epicurean theory. He has indeed been called a modern Stoic, and, allowing for the vagueness of all such phrases, there is much to be said for the description.

An edition of the *Œuvres* of Vauvenargues, slightly enlarged, appeared in the year of his death. There were some subsequent editions, superseded by that of M. Gilbert (2 vols., 1857), which contains some correspondence, some *Dialogues of the Dead*, "characters" in imitation of Theophrastus and La Bruyère, and numerous short pieces of criticism and moralizing. The best comments on Vauvenargues, besides those contained in Gilbert's edition, are to be found in four essays by Sainte-Beuve in *Causeries du lundi*, vols. iii. and xiv., and in Villemain's *Tableau de la littérature française au XVIII^{me} siècle*.

See also M. Paléologue, *Vauvenargues* (1890); and *Selections from . . . La Bruyère and Vauvenargues*, with memoir and notes by Miss Elizabeth Lee (1903).

VAUX, CALVERT (1824–1895), American architect and landscape gardener, was born in London on the 24th of December 1824. He was educated at Merchant Taylors' School and in the office of Lewis N. Cottingham (1787–1847). In 1850 he went to America and became A. J. Downing's architectural partner. In 1856 and 1866 Vaux was associated with F. L. Olmsted in the plans for the improvement of various parks. He designed the Belvidere in Central Park, New York, and built a number of country houses in Newport, besides many town houses and public institutions.

VAUX OF HARROWDEN, THOMAS VAUX, 2ND BARON (1510–1556), English poet, eldest son of Nicholas Vaux, 1st Baron Vaux, was born in 1510. In 1527 he accompanied Cardinal Wolsey on his embassy to France; he attended Henry VIII. to Calais and Boulogne in 1532; in 1531 he took his seat in the House of Lords, and was made Knight of the Bath at the coronation of Anne Boleyn. He was captain of the Isle of Jersey until 1536. He married Elizabeth Cheney, and died in October 1556. Sketches of Vaux and his wife by Holbein are at Windsor, and a finished portrait of Lady Vaux is at Hampton Court. Two of his poems were included in the *Songes and Sonettes of Surrey* (Tottel's *Miscellany*, 1557). They are "The assault of Cupid upon the fort where the lover's hart lay wounded, and how he was taken," and the "Dittye . . . representinge the Image of Deathe," which the gravedigger in Shakespeare's *Hamlet* misquotes. Thirteen pieces in the *Paradise of Dainty Devices* (1576) are signed by him. These are reprinted in Dr A. B. Grosart's *Miscellanies of the Fuller Worthies Library* (vol. iv., 1872).

VAUXHALL, a district on the south bank of the river Thames, in London, England, included in the metropolitan borough of Lambeth. The manor was held by Falkes de Breauté (whence the name, Falkes Hall) in the time of John and Henry III. About 1661 public gardens were laid out here, known as the New Spring Garden, and later as Spring Gardens, but more familiar under the title of Vauxhall Gardens. They soon became the favourite fashionable resort of the metropolis; but as a place of general entertainment they underwent great development from 1732 under the management of Jonathan Tyers (d. 1767) and his sons Thomas and Jonathan. In 1822, with the approval of George IV., who frequented the gardens before his accession, the epithet Royal was added to their title. By the middle of the 19th century, however, Vauxhall had lost its high reputation; in 1859 the gardens were finally closed, and the site was quickly built over.

VAVASSOR (Med. Lat. *valvassor*, *vasvassor*; Fr. *vavassour*, *vavassor*, *vasseur*, &c.), in its most general sense a mediate vassal, *i.e.* one holding a fief under a vassal. The word was, however, applied at various times to the most diverse ranks in the feudal hierarchy, being used practically as the synonym of vassal. Thus tenants-in-chief of the crown are described by the Emperor Conrad (*Lex Lamgob.* lib. iii. tit. 8, § 4) as *valvassores majores* as distinguished from mediate tenants, *valvassores minores*. Gradually the term without qualification was found convenient for describing sub-vassals, tenants-in-chief being called *capitanei* or *barones* (see BARON). Its implication, however, still varied in different places and times. Bracton (lib. i. cap. 8, § 2) ranks the *magnates seu valvassores* between barons and knights; for him they are "men of great dignity," and in this order they are found in a charter of Henry II. (1166). But in the *regestum* of Philip Augustus (fol. 158) we find that five vavassors are reckoned as the equivalent of one knight. Finally, Du Cange quotes two charters, one of 1187, another of 1349, in which vavassors are clearly distinguished from nobles.

The derivation of the word vavassor is very obscure. The fanciful interpretation of Bracton, *vas sortitum ad valetudinem* (a vessel chosen to honour), may be at once rejected. Others would derive it from *vassi ad valvas* (at the folding-doors, *valvae*), *i.e.* servants of the royal antechamber. Du Cange, with more justice, regards it merely as an obscure variant of *vassus*. (W. A. P.)

VAYGACH (variously Waigats, Waigatch, &c.), an island off the Arctic coast of Russia, between it and Novaya Zemlya, bounded S. by the narrow Yugor Strait, and N. by that of Kara. It is roughly oblong in form; its length from S.E. to N.W. is 70 m., and its greatest breadth 28. Its greatest elevation scarcely exceeds 300 ft. For the most part it consists of tundra, with frequent marshes and small lakes. Slight rocky ridges run generally along its length, and the coast has low cliffs in places. The island consists in the main of limestone, and its elevation above the sea is geologically recent. Raised beaches are frequently to be traced. The rocks are heavily scored by ice, but this was probably marine ice, not that of glaciers. Grasses, mosses and Arctic flowering plants are abundant, but there are no trees excepting occasional dwarf willows. Foxes and lemmings are met with, but whereas animals are few, birds are very numerous; a variety of ducks, waders, &c., frequent the marshes and lakes. The island is visited periodically by a few Samoyedes; they formerly considered it sacred, and some of their sacrificial piles, consisting of drift-wood, deer's horns and the skulls of bears and deer, have been observed by travellers. In spite of their conversion to Christianity, the Samoyedes still regard these piles with superstition. The origin of the name Vaygach is as dubious as its orthography; it has been held to be Dutch (*waaien*, to blow, and *gat*, a strait, hence "windy strait") or Russian, in which case it is probably a surname.

Comparatively little was known of the interior of the island until Mr F. G. Jackson made the circuit of it on foot in 1893 (see his *Great Frozen Land*, London, 1895; also H. J. Pearson, *Beyond Petsora Eastward*, London, 1899).

VECTOR ANALYSIS, in mathematics, the calculus of vectors. The position of a point B relative to another point A is specified by means of the straight line drawn from A to B. It may equally well be specified by any equal and parallel line drawn in the same sense from (say) C to D, since the position of D relative to C is the same as that of B relative to A. A straight line conceived in this way as having a definite length, direction and sense, but no definite location in space, is called a *vector*. It may be denoted by $\overrightarrow{AB}$ (or $\overrightarrow{CD}$), or (when no confusion is likely to arise) simply by AB. Thus a vector may be used to specify a displacement of translation (without rotation) of a rigid body. Again, a force acting on a particle, the velocity or momentum of a particle, the state of electric or magnetic polarization at a particular point of a medium, are examples of physical entities which are naturally represented by vectors.

The quantities, on the other hand, with which we are familiar in ordinary arithmetical algebra, and which have merely magnitude and sign, without any intrinsic reference to direction, are distinguished as *scalars*, since they are completely specified by their position on the proper scale of measurement. The mass of a body, the pressure of a gas, the charge of an electrified conductor, are instances of scalar magnitudes. It is convenient to emphasize this distinction by a difference of notation; thus scalar quantities may be denoted by italic type, vectors (when they are represented by single symbols) by "black" or "Clarendon" type.

There are certain combinations of vectors with one another, and with scalars, which have important geometrical or physical significance. Various systems of "vector analysis" have been devised for the purpose of dealing methodically with these; we shall here confine ourselves to the one which is at present in most general use. Any such calculus must of course begin with definitions of the fundamental symbols and operations; these are in the first instance quite arbitrary conventions, but it is convenient so to frame them that the analogy with the processes of ordinary algebra may as far as possible be maintained.

As already explained, two vectors which are represented by equal and parallel straight lines drawn in the same sense are regarded as identical. Again, the product of a scalar m into a vector $\mathbf{A}$ is naturally defined as the vector whose direction is the same as that of $\mathbf{A}$, but whose length is to that of $\mathbf{A}$ in the ratio m, the sense (moreover) being the same as that of $\mathbf{A}$ or the reverse, according as m is positive or negative. We denote it by $m\mathbf{A}$. The particular case where $m=-1$ is denoted by $-\mathbf{A}$, so that a change of sign simply reverses the sense of a vector.

As regards combinations of two vectors, we have in the first place the one suggested by composition of displacements in kinematics, or of forces or couples in statics. Thus if a rigid body receive in succession two translations represented by $\overrightarrow{AB}$ and $\overrightarrow{BC}$, the final result is equivalent to the translation represented by $\overrightarrow{AC}$. It is convenient, therefore, to regard $\overrightarrow{AC}$ as in a sense the "geometric sum" of $\overrightarrow{AB}$ and $\overrightarrow{BC}$, and to write

$$\overrightarrow{AB}+\overrightarrow{BC}=\overrightarrow{AC}.$$

This constitutes the definition of vector *addition*; and it is evident at once from fig. 1 that

$$\overrightarrow{BC}+\overrightarrow{AB}=\overrightarrow{AD}+\overrightarrow{DC}=\overrightarrow{AC}=\overrightarrow{AB}+\overrightarrow{BC}.$$

Hence, $\mathbf{A}$ and $\mathbf{B}$ being any two vectors, we have

$$\mathbf{A}+\mathbf{B}=\mathbf{B}+\mathbf{A}, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

i.e. addition of vectors, like ordinary arithmetical addition, is subject to the "commutative law." As regards subtraction, we define $\mathbf{A}-\mathbf{B}$ as the equivalent of $\mathbf{A}+(-\mathbf{B})$; thus in fig. 1, if $\overrightarrow{AB}=\mathbf{A}$, $\overrightarrow{BC}=\mathbf{B}$, we have

$$\mathbf{A}+\mathbf{B}=\overrightarrow{AC},\ \mathbf{A}-\mathbf{B}=\overrightarrow{DB}.$$

When the sum (or difference) of two vectors is to be further dealt with as a single vector, this may be indicated by the use of curved brackets, *e.g.* $(\mathbf{A}+\mathbf{B})$. It is easily seen from a figure that

$$(\mathbf{A}+\mathbf{B})+\mathbf{C}=\mathbf{A}+(\mathbf{B}+\mathbf{C}), \quad . \quad . \quad . \quad . \quad (2)$$

and so on; *i.e.* the "associative law" of addition also holds.

Again, if m be any scalar quantity, we have

$$m(\mathbf{A}+\mathbf{B})=m\mathbf{A}+m\mathbf{B}, \quad . \quad . \quad . \quad . \quad (3)$$

or, in words, the multiplication of a vector sum by a scalar follows the "distributive law." The truth of (3) is obvious on reference to the similar triangles in fig. 2, where

$$\overrightarrow{OP}=\mathbf{A},\ \overrightarrow{PQ}=\mathbf{B},\ OP'=m\mathbf{A},\ P'Q'=m\mathbf{B}.$$

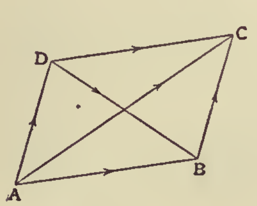

FIG. 1.

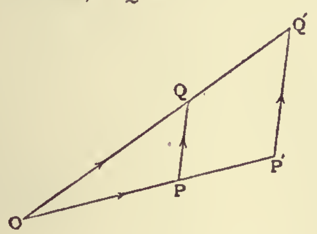

FIG. 2.

It will be noticed that the proofs of (1) and (3) involve the fundamental postulate of the Euclidean geometry.

The definition of "work" in mechanics gives us another important mode of combination of vectors. The product of the absolute magnitudes A, B (say) of two vectors $\mathbf{A}$, $\mathbf{B}$ into the cosine of the angle θ between their directions is called the *scalar product* of the two vectors, and is denoted by $\mathbf{A}.\mathbf{B}$ or simply $\mathbf{AB}$. Thus

$$\mathbf{AB}=AB\cos\theta=\mathbf{BA}, \quad . \quad . \quad . \quad . \quad (4)$$

so that the "commutative law of multiplication" holds here as in ordinary algebra. The "distributive law" is also valid, for we have

$$\mathbf{A}(\mathbf{B}+\mathbf{C})=\mathbf{AB}+\mathbf{AC}, \quad . \quad . \quad . \quad . \quad (5)$$

the proof of this statement being identical with that of the statical theorem that the sum of the works of two forces in any displacement of a particle is equal to the work of their resultant.

For an illustration of the next mode of combination of vectors we may have recourse to the geometrical theory of the rotation of a rigid body about a fixed point O. As explained under MECHANICS, the state of motion at any instant is specified by a vector $\overrightarrow{OI}$ representing the angular velocity. The instantaneous velocity of any other point P of the body is completely determined by the two vectors $\overrightarrow{OI}$ and $\overrightarrow{OP}$, viz. it is a vector normal to the plane of OI and OP, whose absolute magnitude is $OI.OP.\sin\theta$, where θ denotes the inclination of OP to OI, and its sense is that due to a right-handed rotation about OI. A vector derived according to this rule from any two given vectors $\mathbf{A}$, $\mathbf{B}$ is called their *vector product*, and is denoted by $\mathbf{A}\times\mathbf{B}$ or by $[\mathbf{AB}]$. This type of combination is frequent in electro-magnetism; thus if $\mathbf{C}$ be the current and $\mathbf{B}$ the magnetic induction, at any point of a conductor, the mechanical force on the latter is represented by the vector $[\mathbf{CB}]$. It will be noticed in the above kinematical example that if the rôles of the two vectors OI, OP were interchanged, the resulting vector would have the same absolute magnitude as before, but its sense would be reversed. Hence

$$[\mathbf{AB}]=-[\mathbf{BA}], \quad . \quad . \quad . \quad . \quad . \quad (6)$$

so that the commutative law does *not* hold with respect to vector products. On the other hand, the distributive law applies, for we have

$$[\mathbf{A}(\mathbf{B}+\mathbf{C})]=[\mathbf{AB}]+[\mathbf{AC}], \quad . \quad . \quad . \quad . \quad . \quad (7)$$

as may be proved without difficulty by considering the kinematical interpretation.

Various types of triple products may also present themselves, the most important being the scalar product of two vectors, one of which is itself given as a vector product. Thus $\mathbf{A}[\mathbf{BC}]$ is equal in absolute value to the volume of the parallelepiped constructed on three edges OA, OB, OC drawn from a point O to represent the vectors $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ respectively, and it is positive or negative according as the lines OA, OB, OC follow one another in right- or left-handed cyclical order. It follows that

$$\mathbf{A}[\mathbf{BC}]=\mathbf{B}[\mathbf{CA}]=-\mathbf{B}[\mathbf{AC}]=\&c. \quad . \quad . \quad . \quad (8)$$

In order to exhibit the correspondence between the shorthand methods of vector analysis and the more familiar formulae of Cartesian geometry, we take a right-handed system of three mutually perpendicular axes Ox, Oy, Oz, and adopt three fundamental *unit-vectors* i, j, k, having the positive directions of these axes respectively. As regards the scalar products of these unit-vectors, we have, by (4),

$$i^2=j^2=k^2=1,\ jk=kj=ji=0. \quad . \quad . \quad . \quad (9)$$

Any other vector $\mathbf{A}$ is expressed in terms of its scalar projections A_1, A_2, A_3 on the co-ordinate axes by the formula

$$\mathbf{A}=iA_1+jA_2+kA_3. \quad . \quad . \quad . \quad . \quad . \quad (10)$$

For the scalar product of any two vectors we have

$$\mathbf{AB}=(iA_1+jA_2+kA_3)(iB_1+jB_2+kB_3)=A_1B_1+A_2B_2+A_3B_3, \quad (11)$$

as appears on developing the product and making use of (9). In particular, forming the scalar square of $\mathbf{A}$ we have

$$A^2=A_1^2+A_2^2+A_3^2, \quad . \quad . \quad . \quad . \quad (12)$$

where A denotes the absolute value of $\mathbf{A}$.

Again, the rule for vector products, applied to the fundamental units, gives

$$\left.\begin{array}{c}[i^2]=[j^2]=[k^2]=0,\\ [jk]=-[kj]=i,\ [ki]=-[ik]=j,\ [ij]=-[ji]=k.\end{array}\right\} \quad (13)$$

Hence

$$\begin{aligned}[\mathbf{AB}]&=[(iA_1+jA_2+kA_3)(iB_1+jB_2+kB_3)]\\ &=i(A_2B_3-A_3B_2)+j(A_3B_1-A_1B_3)+k(A_1B_2-A_2B_1)\\ &=-[\mathbf{BA}]. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)\end{aligned}$$

The correspondence with the formulae which occur in the analytical theory of rotations, &c., will be manifest. If we form the scalar product of a third vector $\mathbf{C}$ into $[\mathbf{AB}]$, we obtain

$$\mathbf{C}[\mathbf{AB}]=\begin{vmatrix}A_1, & B_1, & C_1\\ A_2, & B_2, & C_2\\ A_3, & B_3, & C_3\end{vmatrix} \quad . \quad . \quad . \quad . \quad . \quad (15)$$

in agreement with the geometrical interpretation already given.

In such subjects as hydrodynamics and electricity we are introduced to the notion of scalar and vector *fields*. With every point P of the region under consideration there are associated certain scalars (*e.g.* density, electric or magnetic potential) and vectors (*e.g.* fluid velocity, electric or magnetic force) which are regarded as functions of the position of P. If we treat the partial-differential operators $\partial/\partial x$, $\partial/\partial y$, $\partial/\partial z$, where x, y, z are the co-ordinates of P, as if they were scalar quantities, we are led to some remarkable and significant expressions. Thus if we write

$$\nabla=\left(i\frac{\partial}{\partial x}+j\frac{\partial}{\partial y}+k\frac{\partial}{\partial z}\right), \quad . \quad . \quad . \quad (16)$$

and operate on a scalar function ϕ, we obtain the vector

$$\nabla\phi=i\frac{\partial\phi}{\partial x}+j\frac{\partial\phi}{\partial y}+k\frac{\partial\phi}{\partial z}. \quad . \quad . \quad . \quad . \quad (17)$$

This is called the *gradient* of ϕ and sometimes denoted by "grad ϕ"; its direction is that in which ϕ most rapidly increases, and its magnitude is equal to the corresponding rate of increase. Thus

$$(\nabla\phi)^2=\left(\frac{\partial\phi}{\partial x}\right)^2+\left(\frac{\partial\phi}{\partial y}\right)^2+\left(\frac{\partial\phi}{\partial z}\right)^2. \quad . \quad . \quad . \quad (18)$$

A repetition of the operation ∇ gives

$$\nabla^2\phi=\frac{\partial^2\phi}{\partial x^2}+\frac{\partial^2\phi}{\partial y^2}+\frac{\partial^2\phi}{\partial z^2}. \quad . \quad . \quad . \quad . \quad (19)$$

In the theory of attractions this expression is interpreted as measuring the degree of *attenuation* of the quantity ϕ at P; if we reverse the sign we get the *concentration*, $-\nabla^2\phi$.

Again, if we form the scalar product of the operator ∇ into a vector A we have

$$\nabla\mathbf{A}=\left(i\frac{\partial}{\partial x}+j\frac{\partial}{\partial y}+k\frac{\partial}{\partial z}\right)(iA_1+jA_2+kA_3)=\frac{\partial A_1}{\partial x}+\frac{\partial A_2}{\partial y}+\frac{\partial A_3}{\partial z}. \quad . \quad (20)$$

If A represent the velocity at any point (x, y, z) of a fluid, the latter expression measures the rate at which fluid is flowing away from the neighbourhood of P. By a generalization of this idea, it is called the *divergence* of **A**, and we write

$$\nabla\mathbf{A}=\text{div }\mathbf{A}. \quad . \quad . \quad . \quad . \quad (21)$$

The vector product $[\nabla\mathbf{A}]$ has also an important significance. We find

$$[\nabla\mathbf{A}]=\left[\left(i\frac{\partial}{\partial x}+j\frac{\partial}{\partial y}+k\frac{\partial}{\partial z}\right)(iA_1+jA_2+kA_3)\right]$$
$$=i\left(\frac{\partial A_3}{\partial y}-\frac{\partial A_2}{\partial z}\right)+j\left(\frac{\partial A_1}{\partial z}-\frac{\partial A_3}{\partial x}\right)+k\left(\frac{\partial A_2}{\partial x}-\frac{\partial A_1}{\partial y}\right) \quad . \quad (22)$$

If **A** represent as before the velocity of a fluid, the vector last written will represent the (doubled) angular velocity of a fluid element. Again if A represent the magnetic force at any point of an electro-magnetic field, the vector $[\nabla\mathbf{A}]$ will represent the electric current. In the general case it is called the *curl*, or the *rotation*, of **A**, and we write

$$[\nabla\mathbf{A}]=\text{curl }\mathbf{A}, \text{ or rot }\mathbf{A}. \quad . \quad . \quad . \quad (23)$$

These definitions enable us to give a compact form to two important theorems of C. F. Gauss and Sir G. G. Stokes. The former of these may be written

$$\int \text{div }\mathbf{A}\,.\,dV=\int \mathbf{A}n\,dS, \quad . \quad . \quad . \quad (24)$$

where the integration on the left hand includes all the volume-elements dV of a given region, and that on the right includes all the surface-elements dS of the boundary, n denoting a unit vector drawn outwards normal to dS. Again, Stokes's theorem takes the form

$$\int \mathbf{A}ds=\int \text{curl }\mathbf{A}\,.\,n\,dS, \quad . \quad . \quad . \quad (25)$$

where the integral on the right extends over any open surface, whilst on the left ds is an element of the bounding curve, treated as a vector. A certain convention is implied as to the relation between the positive directions of n and ds.

It is to be observed that the term "vector" has been used to include two distinct classes of geometrical and physical entities. The first class is typified by a displacement, or a mechanical force. A *polar* vector, as it is called, is a magnitude associated with a certain linear direction. This may be specified by any one of a whole assemblage of parallel lines, but the two "senses" belonging to any one of the lines are distinguished. The members of the second class, that of *axial* vectors, are primarily not vectors at all. An axial vector is exemplified by a couple in statics; it is a magnitude associated with a closed contour lying in any one of a system of parallel planes, but the two senses in which the contour may be described are distinguished. It was therefore termed by H. Grassmann a *Plangrösse* or *Ebenengrösse.* Just as a polar vector may be indicated by a length, regard being paid to its sense, so an axial vector may be denoted by a certain area, regard being paid to direction round the contour. A theory of "Plangrössen" might be developed throughout on independent lines; but since the laws of combination prove to be analogous to those of suitable vectors drawn perpendicular to the respective areas, it is convenient for mathematical purposes to include them in the same calculus with polar vectors. In the case of couples this procedure has been familiar since the time of L. Poinsot (1804). In the Cartesian treatment of the subject no distinction between polar and axial vectors is necessary so long as we deal with congruent systems of co-ordinate axes. But when we pass from a right-handed to a left-handed system the formulae of transformation are different in the two cases. A polar vector (*e.g.* a displacement) is reversed by the process of reflection in a mirror normal to its direction, whilst the corresponding axial vector (*e.g.* a couple) is unaltered.

REFERENCES.—The methods of vector analysis are chiefly used as a means of condensed expression of various important relations which are of frequent occurrence in mathematical physics, more especially in electricity. They are freely employed, for example, in many recent German treatises. The historical development of the subject can only be briefly referred to. The notions of scalar and vector products originated independently with Sir W. R. Hamilton (1843) (see QUATERNIONS) and H. Grassmann (1844), but were associated with various other conceptions of which no use is made in the simplified system above sketched. The present currency of this latter system is due mainly to the advocacy of O. Heaviside and J. W. Gibbs, although for the systematic physical interpretation of the various combinations of symbols which constantly recur in electricity and allied subjects we are indebted primarily to the classical treatise of J. C. Maxwell on *Electricity and Magnetism* (1873). For further details and applications of the calculus reference may be made to the following: O. Heaviside, *Electro-Magnetic Theory* (London, 1894); J. W. Gibbs, *Vector Analysis* (2nd ed., New York, 1907); M. Abraham, *Die Maxwellsche Theorie d. Elektrizität* (Leipzig, 1904); the articles by H. E. Timerding and M. Abraham in vol. iv. of the *Encycl. d. Math. Wiss.* (Leipzig, 1901–2); A. H. Bucherer, *Elemente d. Vektor-Analysis* (Leipzig, 1905). For an account of other systems of vector analysis see H. Hankel, *Theorie d. complexen Zahlensysteme* (Leipzig, 1867); and A. N. Whitehead, *Universal Algebra*, vol. i. (Cambridge, 1898). (H. LB.)

VEDDAHS, or WEDDAHS (from Sanskrit *veddha*, "hunter"), a primitive people of Ceylon, probably representing the *Yakkos* or "demons" of Sanskrit writers, the true aborigines of the island. During the Dutch occupation (1644–1796) they were found as far north as Jaffna, but are now confined to the south-eastern district, about the wooded Bintenna, Badulla and Nilgala hills, and thence to the coast near Batticaloa. They are divided into two classes, the *Kele Weddo* or jungle Veddahs, and the *Gan Weddo*, or semi-civilized village Veddahs. The Veddahs exhibit the phenomenon of a race living the wildest of savage lives and yet speaking an Aryan dialect. Craniometrical evidence strongly favours the theory, now generally accepted, that they represent a branch of the pre-Aryan Dravidians of southern India, and that their ancestors probably made a settlement in the island of Ceylon in prehistoric times, detaching themselves from a migrating horde which passed through the island to find at last a permanent home in the continent of Australia.

The true jungle veddahs are almost a dwarfish race. They are dark-skinned and flat-nosed, slight of frame and very small of skull, and average no more than 5 ft. Their black hair is shaggy rather than lank. They are a shy, harmless, simple folk, living chiefly by hunting; they lime birds, catch fish by poisoning the water, and are skilled in getting wild honey; they have bows with iron-pointed arrows and breed hunting dogs. They dwell in caves or bark huts, and their word for house is Sinhalese for a hollow tree, *rukula.* They count on their fingers, and make fire with the simplest form of fire-drill twirled by hand. They are monogamous, and their conjugal fidelity contrasts strongly with the vicious habits of the Sinhalese. Their religion has been described as a kind of demon-worship, consisting of rude dances and shouts raised to scare away the evil spirits, whom they confound with their ancestors.

The Veddahs are not to be confounded with the Rodiyas of the western uplands, who are a much finer race, tall, well-porportioned, with regular features, and speak a language said to be radically distinct from all the Aryan and Dravidian dialects current in Ceylon. There is, however, in Travancore, on the mainland, a low-caste "Veda" tribe, nearly black, with wavy or frizzly hair, and now speaking a Malayâlim (Dravidian) dialect (Jagor), who probably approach nearer than the insular Veddahs to the aboriginal pre-Dravidian "negrito" element of southern India and Malaysia.

Baily, *Trans. of Ethnol. Soc.*, New Series, vol. ii. (1863); Rolleston, *Trans. of Brit. Ass.* (1872); B. F. Hartshorne, *Fortnightly Review*, New Series, vol. xix. p. 406. The most elaborate monograph is that of Professor Virchow, *Über die Weddas von Ceylon und ihre Beziehungen zu den Nachbarstämmen* (Berlin, 1882). See also E. B. Tylor, *Primitive Culture*; A. Thomson, "Osteology of Veddahs," in *Journ. Anthrop. Institute* (1889), vol. xix. p. 125; L. de Zoysa, "Origin of Veddahs," in *Journal, Ceylon Branch, Royal Asiatic Society*, vol. vii.

VEDDER, ELIHU (1836–), American artist, was born in New York City on the 26th of February 1836. He studied under the genre and historical painter Tompkins H. Matteson (1813–1884), at Sherburne, N.Y., later under Picot, in Paris, and then, in 1857–61, in Italy. After 1867 he lived in Rome, making occasional visits to America. He was elected to full membership in the National Academy of Design, New York, in 1865. He devoted himself to the painting of genre pictures, which, however, attracted only modest attention until the publication, in 1884, of his illustrations to the *Rubaiyat* of Omar Khayyâm; these immediately gave him a high place in the art world. Important decorative work came later, notably the painting symbolizing the art of the city of Rome, in the Walker Art Gallery of Bowdoin College, Maine, and the five lunettes (in the entrance hall) symbolical of government, and the mosaic "Minerva" in the Congressional Library at Washington. Among his better-known pictures are: "Lair of the Sea Serpent," in the Boston Museum of Fine Arts; "Young Marsyas," "Cumaean Sibyl," "Nausicaa," in the collection of J. Pierpont Morgan; and "Genii and Fisherman," in the collection of Martin Brimmer, Boston.

VEDETTE, a French military term (formed from Lat. *videre*, to see), adopted into English and other languages for a mounted sentry or outpost, whose function it is to bring information, give signals or warnings of danger, etc., to the main body of troops.

VEERE, a town in the province of Zeeland, Holland, on the island of Walcheren, 4 m. N.N.E. of Middelburg, with which it is connected by canal (1867–72). It contains several interesting architectural remains of the days of its former prosperity, many of its quaintly gabled old houses dating from the 16th century. There is a fine Gothic church dating from 1348, but subsequently in part destroyed and used for secular purposes; the town hall (1475) has a fine gable filled with sculpture, and contains some interesting antiquities.

VEGA, GARCILASO DE LA (1503–1536), Spanish soldier and poet, was born at Toledo on the 6th of February 1503. His father, Garcilaso (Garcias Laso or Garcilasso) de la Vega, was counsellor of state to Ferdinand and Isabella, and for some time their ambassador at the court of Rome; by his mother he was descended from the illustrious house of Guzman. At the age of seventeen he was attached to the bodyguard of Charles V., and fought against the insurgent *comuneros*, being wounded at the battle of Olias near Toledo. He afterwards served in the north of Italy, and gained great distinction by his bravery at the battle of Pavia in 1525. In the following year he married a lady-in-waiting to Queen Eleanor. He took part in the repulse of the Turks from Vienna in 1529, was present at the coronation of the emperor at Bologna in 1530, and was charged with a secret mission to Paris in the autumn of the same year. In 1531 he accompanied the duke of Alva to Vienna, where, for conniving at the clandestine marriage of his nephew to a maid-of-honour, he was imprisoned on an island in the Danube. During this captivity he composed the fine cancion, "Con un manso ruido de agua corriente y clara." Released and restored to favour in June 1532, he went to Naples on the staff of Don Pedro de Toledo, the newly appointed viceroy, by whom he was twice sent on public business of importance to Barcelona, in 1533 and 1534. After having accompanied the emperor on the expedition to Tunis (1535), where he received two severe wounds, he was employed as a confidential agent at Milan and Genoa in negotiations connected with the proposed invasion of Provence, and joined the expedition when it took the field. Being with Charles in the neighbourhood of Fréjus during the retreat from Marseilles, Garcilaso de la Vega was ordered to storm a fort at Muy, which had checked the advance of the army. In the successful discharge of this duty he was mortally wounded and died twenty-one days afterwards, at Nice (14th of October 1536). His poems were entrusted to his friend Boscan, who was preparing them for publication along with his own when death overtook him in 1540. The volume ultimately appeared at Barcelona in 1543, and has often been reprinted. Garcilaso's share in it consists principally of three *eglogas* or pastorals, which the Spaniards regard as among the finest works of the kind in their language, and which for sweetness of versification and delicacy of expression take a high rank in modern European literature. In addition to the pastorals, there are thirty-seven sonnets, five canciones, two elegies and a blank verse epistle, all influenced by Italian models. The poems rapidly gained a wide popularity; and within a century of their appearance they were edited as classics by Francisco Sanchez (1577), Herrera (1580) and Tamayo de Vargas (1622). An English translation of his works was published by Wiffen in 1823. Garcilaso's delicate charm has survived all changes of taste, and by universal consent he ranks among the most accomplished and artistic of Spanish poets.

See E. Fernández de Navarrete, "Vida de Garcilaso de la Vega," in the *Documentos inéditos para la historia de España*, vol. xvi.; Francesco Flamini, "Imitazioni italiani in Garcilaso de la Vega," in the *Biblioteca delte scuole italiane* (Milano. 1899).

VEGA, GARCILASO DE LA, called "Inca" (*c.* 1535–1616), historian of Peru, was born at Cuzco. His father, Sebastiano Garcilaso (d. 1559), was a cadet of the illustrious family of La Vega, who had gone to Peru in the suite of Pedro de Alvarado, and his mother was of the Peruvian blood-royal, a circumstance of which he was very proud as giving him a right to the title which he claimed by invariably subscribing himself "Inca." About 1560 he removed to Spain, and after serving against the Moors incurred the hatred of Philip II. and was imprisoned at Valladolid. He died in Spain in 1616. A diligent student of the language and traditions of his maternal ancestors, Garcilaso left a valuable work on Peruvian history; the first part, entitled *Comentarios reales que tratan del origen de los Yncas*, was first published at Lisbon in 1609, and the second part, *Historia general del Peru*, in 1617.

His history is a source from which all subsequent writers on the subject have largely drawn, and still continues to be one of the chief authorities on ancient Peru. An English translation by Sir Paul Rycaut was published in 1688; one of the first part of the work by Sir C. R. Markham for the Hakluyt Society (London, 1869–71); and the book has also been translated into French. Garcilaso also wrote a history of Florida, *La Florida del Ynca, historia del adelantado Hernando de Soto* (Lisbon, 1605, and again Madrid, 1723). An edition of his works in seventeen volumes was published at Madrid in 1800. See W. H. Prescott, *History of the Conquest of Peru*, vol. i. (London, 1902); Sir C. R. Markham, *The Incas of Peru* (1910).

VEGA CARPIO, LOPE FELIX DE (1562–1635), Spanish dramatist and poet, was born on the 25th of November 1562 at Madrid. His father and mother, Felix de Vega Carpio and Francisca Hernandez Flores, originally came from the valley of Carriedo in Asturias, where the hamlet of Vega still exists. Lope began his studies at the Theatine college in Madrid, and according to his admiring biographer, Pérez de Montalbán, his precocity was extraordinary. On leaving college he entered the service of Don Jerónimo Manrique, bishop of Avila, and appears to have then begun the composition of his earlier dramas. He quitted the bishop's service to enter the university of Alcalá de Henares, where he devoted himself to what was called philosophy. The date of Lope's matriculation is unknown, as his name does not appear in the university books; but it seems probable that he was in residence between 1576 and 1581. He took part in the expedition to the Azores in 1582, and from 1583 to 1587 was secretary to the marqués de las Navas. In February 1588 he was banished for circulating criminal libels against his mistress, Elena Osorio, whom he has celebrated under the name of Filis. He defied the law by returning to Madrid soon afterwards and eloping with Isabel de Urbina, daughter of Philip II.'s herald; he married her by proxy on the 10th of May 1588, and joined the Invincible Armada, losing his brother in one of the encounters in the Channel. He settled for a short while at Valencia, where he made acquaintance with a circle of young poets who were afterwards to be his ardent supporters in founding the new comedy. He joined the household of the duke of Alva, with whom he remained till 1595. Soon afterwards he lost his wife; he was prosecuted for criminal conversation in 1596, became secretary to the marquis de Malpica (afterwards count de Lemos), and in 1598 married a second wife, Juana de Guardo, by whom he had two children (Carlos, who died in 1612, and Feliciana Felix); but she died, shortly after giving birth to the latter, in 1613. During this wife's lifetime the poet had by a mistress, Micaelade Luxan, two other children—Marcela del Carpio, who became a nun in 1621, and Lope Felix del Carpio y Luxan, who chose the profession of arms and perished at sea about 1634. Widowed a second time in 1613, Lope sought a refuge in the church. After having been for some time affiliated to a tertiary order, he took priest's orders.

At this juncture, about 1614, he was in the very zenith of his glory. A veritable dictator in the Spanish world of letters, he wielded over all the authors of his nation a power similar to that which was afterwards exercised in France by Voltaire. At this distance of time Lope is to us simply a great dramatic poet, the founder of the Spanish theatre; but to his contemporaries he was much more. His epics, his pastorals, his odes, his sonnets, now forgotten, all placed him in the front rank of authorship. Such was his prestige that he dealt with his noble patrons almost on a footing of equality. The duke of Sessa in particular, his Maecenas from 1605 onwards, was also his personal friend, and the tone of Lope's letters to him is one of frank familiarity, modified only by some forms of deference. Lope's fame, too, had travelled abroad: foreigners of distinction passing through Madrid made a point of visiting him; papal legates brought him the compliments of their master; in 1627 Urban VIII., a Barberini, sent him the diploma of doctor of theology in the Collegium Sapientiae and the cross of the order of St John of Jerusalem (whence the poet's titles of "Doctor" and "Frey"). His last days were full of sadness; the death of his son Lope, the elopement of his daughter, Antonia Clara, wounded him to the soul. Montalbán tells us that every Friday the poet scourged himself so severely that the walls of his room were sprinkled with his blood. His death, on the 27th of August 1635, was followed by national mourning.

Leaving out of account certain theories which in the long run greatly influenced his manner of writing, Lope belonged in literature to what may be called the school of good sense; he boasted that he was a Spaniard *pur sang*, and steadfastly maintained that a writer's business is to write so as to make himself understood. When brought face to face with the coterie of the *précieux* and *quintessenciés*, Lope takes the position of a defender of the language of ordinary life, the good old Castilian tongue. In the dispute which arose between the partisans of the two schools of *cultos* and *llanos*, he ranged himself on the side of the latter. In the matter of versification he refuses to admit that the long Italian verse has the advantage of the Castilian octosyllabic. Unfortunately the books that he read, his literary connexions, his fear of Italian criticism, all exercised an influence upon his naturally robust spirit, and, like so many others, he caught the prevalent contagion of mannerism and of pompous phraseology. His literary culture was chiefly Latin-Italian; and, if he defends the tradition of the nation and the pure simplicity of the old Castilian against "los de la nueva poesía," that is to say, the innovators of the school of Góngora and against the jargon of the *cultos*, still he does not wish to be taken for an uninformed person, a writer devoid of classical training: he especially emphasizes the fact that he has passed through the university, and is continually accentuating the difference between the *ingenios cientificos* (those who know Latin) and *legos ignorantes* (ignorant laymen). With what a sense of superiority, for example, does he mention that Cervantes was not to his mind sufficiently *científico* (preface to *Las Fortunas de Diana*), the fact being that Cervantes had been neither at Alcalá nor at Salamanca!

For a rapid survey of the works of Lope, it is convenient to begin with those which the Spaniards include under the name of *Obras Sueltas*, the title of the large collection of the poet's non-dramatic works (Madrid, 21 vols. 4to, 1776–79). We shall enumerate the most important of these, as far as possible in the order of publication. The *Arcadia* (1598), a pastoral romance, inspired by Sannazaro, is one of the poet's most wearisome productions. *La Dragontea* (1598) is a fantastic history in verse of Sir Francis Drake's last expedition and death. *Isidro* (1599), a narrative of the life of Isidore, patron of Madrid, is called a Castilian poem on account of the rhythm in which it is composed—*quintillas* of octosyllabic verse. The *Hermosura de Angélica* (1602), in three books, is a sort of continuation of the *Orlando Furioso*, in octaves after the fashion of the original poem. Finally, the *Rimas* are a miscellany of short pieces. In 1604 was published the *Peregrino en su Patria*, a romance similar in kind to the *Aethiopica* of Heliodorus. Having imitated Ariosto, he proceeded to imitate Tasso; but his *Jerusalem Conquistada* (1609) has preserved nothing of the art shown in its model, and is an insipid performance. Next follows the *Pastores de Belen* (1612), a pious pastoral, dedicated to his son Carlos, which forms a pendant to his secular *Arcadia*; and incidental pieces published in connexion with the solemnities of the beatification and canonization of St Isidore in 1620 and 1622. It is enough to mention *La Filomena* (1621), *La Circe* (1624) and other poems published about the same date, as also the four prose novels, *Las Fortunas de Diana, El Desdichado por la Honra, La Más Prudente Venganza* and *Guzmán el Bravo*. The great success of the *Novelas Exemplares* of Cervantes (1613) had stimulated Lope, but in this instance at least the *científico* was completely defeated by the *lego*: Lope's novels have none of the grace, naturalness or interest which characterize those of his rival. The last important work which has to be mentioned before we leave the narrative poetry of Lope is the *Laurel de Apolo* (1630). This piece describes the coronation of the poets of Spain on Helicon by Apollo, and it is more meritorious as a bibliographical manual of Spanish poetry at that time than as genuine poetry. One other *obra suelta*, closely akin to Lope's dramatic works, though not, properly speaking, a drama, is *La Dorotea* (1632). Lope describes it as an "action in prose," but it is rather a "romance in dialogue"; for, although divided into acts, the narrative is dramatic in form only. Of all Lope's productions *Dorotea* shows most observation and study; the style also is unusually simple and easy. Of all this mass of *obras sueltas*, filling more than twenty volumes, very little (leaving *Dorotea* out of account) holds its own in the judgment of posterity. The lyrical element alone retains some vitality. From the *Rimas* and other collections of detached pieces one could compile a pleasing anthology of sonnets, epistles, elegies and romances, to which it would be proper to add the *Gatomaquia*, a burlesque poem published along with other metrical pieces in 1634 by Lope under the pseudonym of Tomé de Burguillos. But here the list would end.

It is, however, to his dramatic writings that Lope owes his eminent place in literary history. It is very curious to notice how he himself always treats the art of comedy-writing as one of the humblest of trades (*de pane lucrando*), and protests against the supposition that in writing for the stage his aim is glory and not money. The reason is not far to seek. The Spanish drama, which, if not literally the creation of Lope, at least owes to him its definitive form—the three-act comedy—was totally regardless of the precepts of the school, the pseudo-Aristotelianism of the doctors of the period. Lope accordingly, who stood in awe of the criticism of the *científicos*, felt bound to prove that, from the point of view of literary art, he attached no value to the "rustic fruits of his humble *vega*." In his *Arte Nuevo de hacer comedias en este tiempo* (1609), Lope begins by showing that he knows as well as any one the established rules of poetry, and then excuses himself for his inability to follow them on the ground that the "vulgar" Spaniard cares nothing about them. "Let us then speak to him in the language of fools, since it is he who pays us." Another reason which made it necessary for him to speak deprecatingly of his dramatic works, is the circumstance that the vast majority of them were written in haste and to order. The poet does not hesitate to confess that "more than a hundred of my comedies have taken only twenty-four hours to pass from my brain to the boards of the theatre." Perez de Montalbán, who has a great admiration for this kind of cleverness, tells how, at Toledo, on a certain occasion, Lope composed fifteen acts in fifteen days—that is to say, five entire comedies, which he read to his friends step by step with the process of their composition. On another occasion, when pressed by a manager who wanted something for the carnival, Lope took Montalbán as a collaborator; the two friends parcelled out the comedy between them, Lope undertaking the first act, Montalbán the second, and the third, to save time, was divided between them. In two days they had finished the first two acts, and on the third Montalbán rose at two in the morning and at eleven he had finished. Then he went in search of Lope, who, when questioned as to his progress, replied: "I got up at five, finished the act, breakfasted, wrote an epistle of fifty tercets, and have now finished watering the garden, and a rather tough business it has been." Nevertheless, Lope did write dramas in which the plan is more fully matured and the execution more carefully carried out; still, hurried composition and reckless production are after all among the distinctive marks of his theatrical works. Towards the close of his career Lope somewhat modified the severe and disdainful judgments he had formerly passed upon his dramatic performances; he seems to have had a presentiment that posterity, in spite of the grave defects of his work in that department, would nevertheless place it much higher than *La Dragontea*, the *Jerusalem Conquistada* and other works of which he himself thought so much. We may certainly credit Lope with creative power, with the instinct which enabled him to reproduce the facts of history or those supplied by the imagination in a multitude of dramatic situations with an astonishing cleverness and flexibility of expression; but unfortunately, instead of concentrating his talent upon the production of a limited number of works which he might have brought to perfection, he dissipated it, so to say, and scattered it to the winds.

The catalogue of Lope's comedies has been drawn up by himself; and, in spite of some discrepancies in his figures, it is established that up to 1604 he had composed, in round numbers, as many as 230. In 1609 the figure had risen to 483, in 1618 to 800, in 1620 to 900, in 1625 to 1070, and in 1632 to 1500. Ultimately Montalbán in the *Fama Postuma* (1636) set down the total of Lope's dramatic productions at 1800 plays and more than 400 *autos sacramentales*. Of this number there are 637 plays which are known to us by their titles (from the lists of the *Peregrino*); but the printed or MS. text of only 458 is actually accessible, besides some 50 *autos* and a few *entremeses*. Very many of these pieces were printed during Lope's lifetime, either in collections of *varios autores* or as separate issues by booksellers who surreptitiously bought from the actors the manuscripts of their rôles or else caused the unpublished comedy to be written down from memory by persons whom they sent to attend the first representation. Such pieces therefore as do not figure in the collection published under Lope's own direction or under that of his friends cannot be regarded as perfectly authentic, and it would be unfair to hold their author responsible for all the faults and defects they exhibit. On the other hand, there exist comedies in Lope's own handwriting which have not yet been printed.

The classification of this enormous mass of dramatic literature is a task of great difficulty, inasmuch as the terms usually employed, such as comedy, tragedy and the like, do not apply here. There is not explicitness enough in the division current in Spain, which recognizes three categories:—(1) *comedias de capa y espada*, the subjects of which are drawn from everyday life and in which the persons appear as simple *caballeros*; (2) *comedias de ruido* or *de teatro*, in which kings and princes are the leading characters and the action is accompanied with a greater display of dramatic machinery; (3) *comedias divinas* or *de santos*. Some other arrangement must be attempted. In the first place, Lope's work belongs essentially to the drama of intrigue; be the subject what it may, it is always the plot that determines everything else. Lope in the whole range of his dramatic works has no piece comparable to *La Verdad Sospechosa* of Ruiz de Alarcón, the most finished example in Spanish literature of the comedy of character; and the comedy of manners is represented only by *El Galán Castrucho*, *El Anzuelo de Fenisa*, and one or two others. It is from history, and particularly Spanish history, that Lope has borrowed more than from any other source. It would in fact be difficult to say what national and patriotic subjects, from the reign of the half-fabulous King Pelayo down to the history of his own age, he has not put upon the stage. But it is to the class of *capa y espada*—also called *novelesco*, because the subjects are almost always love intrigues complicated with affairs of honour—that Lope's most celebrated plays belong. In these he has most fully displayed his powers of imagination (the subjects being all invented) and his skill in elaborating a plot. Among the plays of this class which are those best known in Europe, and most frequently imitated and translated, may be specially mentioned *Los Ramilletes de Madrid*, *La Boba para los Otros y Discreta para si*, *El Perro del Hortelano*, *La Viuda de Valencia*, and *El Maestro de Danzar*. In some of them Lope has sought to set forth some moral maxim, and illustrate its abuse by a living example. Thus, on the theme that "poverty is no crime," we have the play entitled *Las Flores de Don Juan*, in which he shows in the history of two brothers the triumph of virtuous poverty over opulent vice; at the same time he attacks indirectly the institution of primogeniture, which often places in the hands of an unworthy person the honour and substance of a family when the younger members would be much better qualified for the trust. Such pieces are, however, rare in Lope's repertory; in common with all other writers of his order in Spain, with the occasional exception of Ruiz de Alarcón, his sole aim is to amuse and stir his public, not troubling himself about its instruction. The strong point of such writers is and always will be their management of the plot. As has been said by Le Sage, a good judge: "The Spaniards are our masters in the art of planning and skilfully working out a plot; they know how to set forth their subject with infinite art and in the most advantageous light." It is not necessary to dwell here upon the other varieties of comedy represented in Lope's works, that is, the *comedias divinas*, *fiestas* (mythological dramas for the most part), *entremeses* and *autos*. In none of them has he produced anything of the highest order, or even comparable to the better performances of his contemporaries and successors.

To sum up, Lope found a poorly organized drama, plays being composed sometimes in four acts, sometimes in three; and, though they were written in verse, the structure of the versification was left far too much to the caprice of the individual writer. The style of drama then in vogue he adopted, because the Spanish public liked it. The narrow framework it afforded he enlarged to an extraordinary degree, introducing everything that could possibly furnish material for dramatic situations,—the Bible, ancient mythology, the lives of the saints, ancient history, Spanish history, the legends of the middle ages, the writings of the Italian novelists, current events, Spanish life in the 17th century. Before him manners and the conditions of persons and characters had been barely sketched; with fuller observation and more careful description he created real types, and gave to each social order the language and drapery appropriate to it. The old comedy was awkward and poor in its versification; he introduced order into the use of all the forms of national poetry, from the old romance couplets to the rarest lyrical combinations borrowed from Italy. Hence he was justified in saying that those who should come after him had only to go on along the path which he had opened up.

Pérez Pastor, *Proceso de Lope de Vega por libelos contra unos cómicos* (Madrid, 1901), to which is appended *Datos desconocidos para la vida de Lope de Vega*. For Lope's literary theories and doctrine of dramatic art, reference may be made to M. Menéndez y Pelayo, *Historia de las Ideas Estéticas en España*, and to A. Morel Fatio, *La Comédie espagnole du XVII^me siècle* (8vo, Paris, 1885). The *Obras Sueltas* were published by Francisco Cerdá y Rico (21 vols. 4to, Madrid, 1776–1779). A complete edition of the *Obras de Lope de Vega*, edited by M. Menéndez y Pelayo, has been undertaken by the Spanish Academy. Rennert's biography contains an admirable bibliography of Lope's plays and *autos*.

(A. M.-Fa.; J. F.-K.)

VEGETABLE (Late Lat. *vegetabilis*, full of life, animating, from *vegetare*, frequentative of *vegere* to quicken, arouse, *vegetus*, vigorous, active, cf. *vigor*, strength, vigour, &c.), a word used as a general term for plants (*q.v.*), and specifically, in popular language, of such plants as can be eaten by man or animals, whether cooked or raw, and whether the whole of such plants are edible, or only the leaves or the roots or tubers. Among such edible or culinary plants or portions of plants, a further distinction is made popularly between "fruits" and "vegetables," for which see FRUIT.

For the botany and cultivation of vegetables see under the specific names, *e.g.* POTATO, TURNIP, &c. &c., and generally, HORTICULTURE.

VEGETABLE MARROW, *Cucurbita Pepo*, var. *ovifera*, the most important of the gourds (*q.v.*), used as an esculent, furnishing in good seasons a very large supply for the table. They are best when eaten quite young and not over-boiled, the flesh being then tender, and the flavour sweet and nutty. The *Custard Marrow*, or crown gourd, bears a peculiar-looking flattened fruit with scalloped edges, which has a sweeter and less nutty flavour than the true marrow. A very distinct form known as Pen-y-Byd has a delicate creamy white nearly globular fruit, with a firm flesh. The bush marrows are more bushy in habit and taller and more sturdy in growth.

Vegetable marrows require a warm situation and a rich soil free from stagnant moisture. They do well on a rubbish or old-dung heap, or in a warm border on little hillocks made up with any fermenting material, to give them a slight warmth at starting. The seeds should be sown in a warm pit in April, and forwarded under glass, but in a very mild heat; the plants must be shifted into larger pots, and be gradually hardened previous to being planted out, when the mild weather sets in in May or June. The use of hand-glasses makes it possible to transplant earlier than would otherwise be advisable. The seeds may be sown early in May in pots under a hand-glass, or towards the end of May in the open ground, if heat is not at command. The true vegetable marrow bears fruit of an oblong-elliptical shape, about 9 in. long, pale-greenish while young, with whitish flesh, and scarcely any indication of ribs; when mature it is of a pale yellow colour. There is a variety which is more oblong, grows to 15 or 18 in., and has the surface slightly marked by irregular longitudinal obtuse ribs. The shoots may be allowed to run along the surface of the ground, or they may be trained against a wall or paling, or on trellises. As the gourds cross readily, care is necessary to keep any particular variety true. One of the best vegetable marrows is called Moore's Vegetable Cream.

VEGETARIANISM, a comparatively modern word, which came into use about the year 1847, as applied to the practice of living upon foods from which fish, flesh and fowl are excluded. There have from time to time been various sects or schools of thought that have advocated narrower views. Some of these have excluded all animal products—such as milk and eggs and cheese. Some have excluded all cooked foods, and have preached the virtues of fruits and nuts and grains in their natural ripe state. Some have abstained from all underground-grown roots and tubers, and have claimed special benefits from using only those fruits and vegetables that are grown in the sunlight. Some have given up all grain and pulse foods, and have declared that old age can be best resisted by living entirely upon fruits, salads, nuts, soft water and milk products. Some have added fish to their dietary; but, speaking generally, all who are called vegetarians will be found to abstain from the use of flesh and fowl and almost invariably also from fish as food.

The fact, however, must not be overlooked that while vegetarian societies claim as "vegetarians" all who abstain from flesh-foods, there is a large and growing number of people who repudiate the name of "vegetarian" because of its associations, but who none the less, for some of the reasons detailed below, abstain from eating anything that has been killed. The Order of the Golden Age, for example, with its headquarters at Barcombe Hall, Paignton, South Devon, adopted the words "Fruitarian" and "Fruitarianism" to denote the dietary of its members. The rule laid down by the Order is abstinence so far as possible from all foods which are obtained by the cruel infliction of pain, and the minimum that is set is complete "abstinence from flesh and fowl," while net-caught fish may be used by associate members.

The reasons that are advanced for the practice of fruitarianism or vegetarianism are very comprehensive, but the principal ones may be considered to be the following:—

1. *Health*.—(α) On the ground that animals are affected by diseases which are communicable, and are actually communicated, to man by the ingestion of their flesh, *e.g.* parasites, tuberculosis; (β) on the ground that the flesh of artificially fed animals is full of excretory substances, and that, therefore, *under modern conditions*, flesh-eating is injurious, and may be a cause of excretory substance and uric acid deposits or rapid tissue-destroying diseases in man; *e.g.* gout, cancer.
2. *Economy*.—On the ground that the assimilable nutriment from a given weight of selected fruit and grain and nut and vegetable foods will cost less than the same nutriment obtained from flesh foods.
3. *Social Economy*.—On the ground that an acre of cultivable land under fruit and vegetable cultivation will produce from two to twenty times as much food as if the same land were utilized for feeding cattle.
4. *Racial Improvement*.—On the ground that the aim of every prosperous community should be to have a large proportion of hardy country yeomen, and that horticulture and agriculture demand such a high ratio of labour, as compared with feeding and breeding cattle, that the country population would be greatly increased by the substitution of a fruit and vegetable for an animal dietary.
5. *Character Improvement*.—On the ground that after the virtues of courage and valour and fearlessness have been taught in the lower stages of evolution, the virtue of gentle humaneness and extended sympathy for all that can suffer, should be taught in the higher cycles of the evolutionary spiral. Flesh-eating entailing necessarily an immense volume of pain upon the sentient animal creation should be abstained from by the "higher classes" in the evolutionary scale.

Organizations have been established to advocate this method of living under the name of "Vegetarian Societies" in many countries—chiefly the United Kingdom, America, Germany, France, Austria, Holland and Australia. Propagandism is carried on by lectures, literature, cookery demonstrations and restaurants. In England, the oldest and one of the most important societies is "The Vegetarian Society," of which the headquarters are at Oxford Street, Manchester. There are also several small London societies, and an active London Association. A few provincial towns, too, have small societies. An attempt has been made to organize the various vegetarian societies of the world under the title of "The Vegetarian Federal Union." The headquarters of the London societies and of the "Union" are at Memorial Hall, Farringdon Street, E.C.

There are nominally about 35 organized societies in existence, but the extent to which public opinion and practice in the matter of dietary has been affected by vegetarianism is not to be gauged by the membership of such organizations. There are in England a number of vegetarian restaurants and boarding-houses, one hospital and one or two sanatoria. In Germany and America there are many institutions where flesh is only prescribed in special cases. Flesh food is not included in the dietary of the chief hospitals and orphanages of the native states of India, excepting in the wards devoted to Europeans.

The athletic side of the movement has been represented in national and international races by vegetarians winning the Berlin and Dresden walking match (125 m.), the Carwardine Cup (100 m.) and Dibble Shield (6 hours) cycling races (1901 and 1902), the amateur championship of England in racquets and in tennis (held by Mr Eustace Miles for a series of years), the cycling championship of India (3 years), half-mile running championship of Scotland (1896), world's amateur cycle records for all times from 4 hours to 13 hours (1902), 100 miles championship Yorkshire Road Club (1899, 1901).

In the religious world the Seventh-Day Adventists (who are connected with many sanatoria and the manufacture of food specialities) and some Bible Christians, the worshippers of Vishnu and the Swami Narang and Vishnoi sects, amongst others, preach abstinence from flesh food. The Salvation Army, the Tolstoyans and the Doukhobors encourage it. A number of orders in the Roman Catholic church (*e.g.* the Trappists) and in the Hindu faith (*e.g.* the Dadupanthi Sadus) are pledged abstainers.

The general question of food values is discussed in the article DIETETICS; see also NUTRITION. But there is no doubt that, whatever may be the view taken as to the extreme theory of vegetarianism, it has had considerable effect in modifying the excessive meat-consuming régime of previous days, and in introducing new varieties of vegetable cooking into the service of the table.

The literature on the subject is considerable, but the two classics are perhaps *The Ethics of Diet*, by Howard Williams, and *The Perfect Way in Diet*, by Dr Anna Kingsford. In former years the "Vegetarian Society" was the most active in producing literature, but since about 1901 the Order of the Golden Age has come to the front with new and up-to-date books, booklets and leaflets, and the Ideal Publishing Union has reprinted much of the earlier literature. The chief periodicals are the *Vegetarian* (weekly), the *Herald of the Golden Age* (monthly), the *Vegetarian Messenger* (monthly), the *Vegetarian* (American monthly), the *Children's Garden* (monthly). (J. O.)

VEGETIUS (FLAVIUS VEGETIUS RENATUS), a celebrated military writer of the 4th century. Nothing is known of his life, station and military experience, save that in MSS. he is called *vir illustris* and also *comes*. His treatise, *Epitoma rei militaris, sive institutorum rei militaris libri quinque*, was dedicated to the reigning emperor (? Theodosius the Great). His sources, according to his own statement, were Cato, Cornelius Celsus, Frontinus, Paternus and the imperial constitutions of Augustus, Trajan and Hadrian. The book, which is a confused and unscientific compilation, has to be used with great caution, but is none the less invaluable to the student of the ancient art of war.

The first book is a plea for army reform, and vividly portrays the military decadence of the empire. The third contains a series of military maxims which were (rightly enough, considering the similarity in the military conditions of the two ages) the foundation of military learning for every European commander, from William the Silent to Frederick the Great. When the French Revolution and the "nation in arms" came into history, we hear little more of Vegetius. Some of the maxims may be mentioned here as illustrating the principles of a war for limited political objects (see ARMY) with which he deals. "All that is advantageous to the enemy is disadvantageous to you, and all that is useful to you, damages the enemy"; "No man is to be employed in the field who is not trained and tested in discipline"; "It is better to beat the enemy through want, surprises and care for difficult places (*i.e.* through manœuvre) than by a battle in the open field"—maxims that have guided the leaders of professional armies in all countries and at all times, as witness the Chinese generals Sun and Wu (see E. F. Calthrop, *The Book of War*, London, 1908). His "seven normal dispositions for battle," once in honour amongst European students of the art of war, are equally ludicrous if applied to present-day conditions. His book on siegecraft is important as containing the best description of late empire and medieval siege matters, &c., and from it amongst other things we learn details of the siege engine called *onager*, which afterwards played a great part in sieges. The fifth book is an account of the material and personnel of the Roman navy.

In manuscript, Vegetius's work had a great vogue from the first, and its rules of siegecraft were much studied in the middle ages. It was translated into English, French and even Bulgarian before the invention of printing. The first printed editions are assigned to Utrecht (1473), Cologne (1476), Paris (1478), Rome (in *Veteres de re mil. scriptores*, 1487), and Pisa (1488). A German translation by Ludwig Hohenwang appeared at Ulm in 1475. Vegetius's position as the premier military critic was thenceforward assured. As late as the 18th century we find so eminent a soldier as Marshal Puységur basing his own works on this acknowledged model, and the famous Prince de Ligne wrote "C'est un livre d'or." The fullest and most important modern edition is that of Karl Lang (Leipzig, 1869). An English version through the French was published by Caxton in 1489. For a detailed critical estimate of Vegetius's works and influence see Max Jähns, *Gesch. der Kriegswissenschaften*, i. 109–125.

VEGLIA (Slavonic, *Krk*), an island in the Adriatic Sea, off the west coast of Croatia, from which it is separated by the Canale della Morlacca. It is situated in the Gulf of Quarnero, and is separated from the island of Cherso, lying on the S.W., by the Canale di Mezzo. Together with Cherso and Lussin, the three principal islands of the Quarnero group, it forms the administrative district of Lussin, belonging to the Austrian crownland of Istria. Veglia is the largest island of the Quarnero group, having an area of 146 sq. m. It is 24 m. long and about 14 m. across at its widest part. The surface is mostly rugged and mountainous; but the central, southern and western districts are fertile. The principal town is Veglia (pop. 2074), situated on the south-west coast, with a good harbour and an interesting cathedral.

VEII, an ancient town of Etruria, Italy, situated about 10 m. N. by W. of Rome by road. It is mentioned in the earliest history of Rome as a constant enemy, being the nearest Etruscan city to Rome. The story of the slaughter of the Fabii, who had encamped in the territory of Veii, and of whom but one boy escaped, is well known. After constant warfare, the last war (the fourteenth, according to the annalists) broke out in 406 B.C. The Romans laid siege to the city, and, after a ten years' siege, M. Furius Camillus took it by storm in 396, by means, so we are told, of a tunnel leading into the citadel. According to the legend, the *emissarium* of the Alban Lake was constructed in obedience to the Delphic oracle, which declared that, until it was drained, Veii could not be taken. The territory of Veii was three years afterwards divided among the Roman plebs. Veii is mentioned in connexion with the defeat of the Romans at the Allia in 390 B.C., after which many Roman soldiers fled there, while a project was actually broached for abandoning Rome for Veii, which was successfully opposed by Camillus. From this time onwards we hear little or nothing of Veii up to the end of the Republic. Propertius speaks indeed of the shepherds within its walls. Augustus, however, founded a municipality there (*municipium Augustum Veiens*), inscriptions of which have been found down to the time of Constantius, after which, at some date unknown, the place was deserted. The medieval castle of Isola Farnese, on a hill to the south of the city,[1] is first mentioned in a document of A.D. 1003; but Veii itself had disappeared to such an extent that its very site was uncertain, though some scholars identified it correctly, until the excavations of the 19th century finally decided the question. Veii was not on a high road, but was reached by branch roads from the Via Clodia. The site is characteristic—a plateau, the highest point of which is 407 ft. above sea-level, divided from the surrounding country by deep ravines, and accessible only on the west, where it was defended by a wall and fosse. Remains of the city walls, built of blocks of tufa 2 ft. high, may be traced at various points in the circuit. The area covered measures about 1 sq. m. There are no other remains on the site of the city earlier than the Roman period, and these are now somewhat scanty. The site of the Forum has been discovered on the west side of the plateau; a statue of Tiberius, now in the Vatican, and the twelve Ionic columns now decorating the colonnade on the W. side of the Piazza Colonna at Rome were found there. The acropolis was at the eastern extremity of the site, where the two ravines converge; it is connected with the rest of the plateau by a narrow neck, and here a large number of ex-votos in terra-cotta, indicating the presence of a temple, and dating at earliest from the 3rd century B.C., have been found. The first discovery of them was made in 1655–1667, when remains of the temple (of Juno?) to which they belonged were also found (R. Lanciani, *Pagan and Christian Rome*, London, 1892, p. 64). In the deep ravine to the N. of the site of the town, traversed by the Cremera brook, are the ruins of two ancient bridges and of some baths of the Roman period; and here is also the Ponte Sodo, a natural tunnel, artificially enlarged, through which the stream passes. Outside the city tombs have been discovered at various times. The earliest belonged to the Villanova period (8th and 9th centuries, B.C.), probably before the coming of the Etruscans. Others are cut in the rock and are Etruscan. The most famous is the Grotta Campana found in 1843, which contains paintings on the walls with representations of animals, among the earliest in Etruria. There are also several tumuli. To a later period belongs a columbarium cut in the rock, with niches for urns.

See L. Canina, *L'antica città di Veio* (Rome, 1847); G. Dennis, *Cities and Cemeteries of Etruria* (London, 1883), i. 1 sqq.

(T. As.)

VEIL (O.Fr. *veile*, mod. *voile*, from Lat. *velum*, cloth, awning, sail), a cloth or piece of other fabric used as a means of concealing something from the view, as in the veils of the Jewish tabernacle, which hung before the Holy Place, and before the Most Holy Place. The word is, however, chiefly used of a covering for the face and head, as worn by women. The veiling of the face by women is a practice among the Mohammedan races of the East and among those peoples which have come under the influence of Islam. It is observed only when outside the harem and not by slaves or by the very poor, and rarely by the Bedouin women. The face-veil (*burka'*) is a long strip of white muslin covering the whole of the face except the eyes and reaching nearly to the feet. Among the poorer classes the *burka'* is made of coarse black crêpe, or the *tarhah*, the head-veil, is drawn round the lower part of the face. There is also the double veil or *yashmak*, serving as a head- and face-veil (see INDIA, § *Indian Costume*). In European countries the veil has played a large part in the head-dress of women. It took many shapes in the early middle ages and could be brought over the face as a covering or protection. Later it became a mere ornamental appendage, hanging down from the high, peaked and elaborate head-dresses then worn. In modern times it has become a piece of gauze, lace or net attached to the hat or bonnet and used as a protection against dust, light or wind.

VEINS, in anatomy. The veins (Lat. *vena*) are blood vessels which return the blood from the capillaries toward the heart. As they approach that organ they join together to form larger and larger trunks. In man and other mammals three venous systems are recognized: (1) the *general venous system*; (2) the *pulmonary system*; and (3 the *hepatic portal system*. (See also VASCULAR SYSTEM.)

The *general venous system* consists of superficial and deep veins; the former lie in the superficial fascia and are often visible through the skin. They are usually accompanied by lymphatic vessels though not as a rule by arteries, and, sooner or later, they empty their blood into the deep veins, often passing through special openings in the deep fascia to do so. The deep veins always accompany arteries, and are therefore known as *venae comites*. With small and medium-sized arteries—that is to say, arteries whose diameter is not much greater than that of an ordinary lead pencil—there are two of these venae comites, one on each side, connected by occasional cross communications, but arteries of a larger calibre have only one companion vein. In the scalp and face the superficial veins are remarkable for accompanying, more or less closely, corresponding arteries—more or less closely because the arteries in this region are very tortuous (see ARTERIES), and so are sometimes near their veins and sometimes far away, since the veins run a comparatively straight course. *Frontal*, *superficial temporal*, *posterior auricular* and *occipital veins* are found in the scalp, their names indicating the areas they drain. Like all other superficial veins, they anastomose freely with one another and also at certain places communicate, through foramina in the skull, with the intracranial blood sinuses; these communications are known as *emissary veins*, and act as safety-valves to the sinuses. The frontal vein on the forehead passes down on the inner side of the eyelids, where it is known as the *angular*, and then becomes the *facial vein*, which runs down to an inch in front of the angle of the jaw, whence it passes into the neck to join the common facial. In the greater part of its course it lies some distance behind the facial artery. The *superficial temporal vein* runs down in front of the ear, where it joins the internal maxillary vein from the pterygoid plexus and so forms the *temporo-maxillary trunk*, which passes down, embedded in the parotid gland, to about the angle of the jaw. Here it divides into an anterior branch, which joins the facial vein to form the common facial, and a posterior, which receives the posterior auricular vein and in this way forms the external jugular.

The *external jugular vein* is easily recognized through the skin and platysma muscle on the side of the neck, and eventually pierces the deep fascia above the middle of the clavicle to join the subclavian vein. The *occipital vein* sinks deeply into the back of the neck and so forms the beginning of the vertebral vein.

The *intracranial blood sinuses* lie between two layers of the dura mater and differ from the veins in having fibrous walls which do not contract or expand. The *superior longitudinal sinus* runs along the upper margin of the falx cerebri (see BRAIN), while the inferior longitudinal sinus runs along the lower margin; these drain the surface of the brain, and the blood passes backward in both. Where the falx meets the tentorium cerebelli, the inferior longitudinal sinus receives the *veins of Galen* from the interior of the brain and then passes backward as the *straight sinus* to join the superior longitudinal sinus at the internal occipital protuberance (see SKULL). This meeting-place is known as the *torcular Herophili*, and from it the blood passes outward and downward through the right and left *lateral sinuses*, which groove the cranium (see SKULL) until they

[1] Some have considered Isola Farnese to have been the arx of Veii, but this is unlikely.

reach the posterior lacerated foramina, through which they pass to form the beginning of the internal jugular veins. Most of the blood from the base of the brain passes into the *cavernous sinuses* which lie in the middle cranial fossa, one on each side of the pituitary fossa. These receive the ophthalmic veins from the orbit in front and, after running backward for about an inch, divide into the *superior* and *inferior petrosal sinuses*, the former of which joins the lateral sinus within the cranium, but the latter runs to the posterior lacerated foramen, after passing through which it joins the lateral sinus, which is now becoming the internal jugular vein.

The *internal jugular vein* (fig. 5, I.J.) thus formed runs down at first behind and then to the outer side of the internal and common carotid arteries and at the root of the neck joins the subclavian vein of its own side to form the innominate vein. In its course down the neck it receives the common facial vein already mentioned, as well as tributaries from the tongue, pharynx, larynx and thyroid body. The deep veins of the head and face tend to form plexuses rather than venae comites; of these, *pterygoid*, *deep temporal*, *pharyngeal* and *suboccipital plexuses* are recognized.

Veins of the Upper Extremity.—On the dorsum of the hand and in front of the wrist superficial venous plexuses are easily seen through the skin. From these the blood passes up the forearm chiefly on its flexor surface by the *radial*, *median* and *anterior* and *posterior ulna veins*. Just below the bend of the elbow the median vein communicates with the deep veins and then divides into two branches like the limbs of a Y. Of these the inner is the *median basilic* and is noticeable as the vein from which patients were usually bled, while the outer is the *median cephalic*. After a course of an inch or two the median basilic is joined by the anterior and posterior ulnar veins and the median cephalic by the radial. After this junction the median basilic is continued up the inner side of the arm as the *basilic* which pierces the deep fascia about the middle of the arm and in the axilla joins the venae comites of the brachial artery to form the *axillary vein*, which lies on the inner side of its artery. The median cephalic vein after joining the radial runs up the outer side of the arm as the *cephalic* and a little below the clavicle passes through the costo-coracoid membrane to enter the upper part of the axillary vein. At the outer border of the first rib the axillary vein becomes the subclavian (fig. 5, S.), which lies in front of and below its artery and is separated from it by the scalenus anticus muscle. The arrangement of the superficial veins, especially in front of the elbow, is liable to great variation and often differs on the right and left sides of the same body.

Veins of the Lower Extremity.—The superficial veins of the lower extremity begin in a venous arch on the dorsum of the foot. From the inner extremity of this the *internal saphenous vein* runs up, in front of the inner ankle, along the inner side of the leg, and, passing behind the inner side of the knee, continues up the thigh, gradually working forward until it reaches the *saphenous opening* in the deep fascia of the thigh a little below the spine of the pubis. Here it pierces the deep fascia (*fascia lata*) to enter the common femoral vein. In this long course it has many valves and receives numerous tributaries, one of which, the *saphenous collateral*, runs up nearly parallel to it and on its outer side and joins it just below the saphenous opening. From the inner end of the dorsal arch of the foot the *external saphenous vein* runs up behind the outer ankle along the mid line of the calf to pierce the deep fascia in the popliteal space behind the knee to open into the popliteal vein. Among the deep veins venae comites are found until the popliteal artery is reached, while above this *superficial*, *deep* and *common femoral veins* accompany their respective arteries. In the groin the common femoral vein lies on the inner side of its artery.

Veins of the Abdomen.—The common femoral vein, after passing deep to Poupart's ligament, becomes the *external iliac* (fig. 5, E.I.) which runs along the brim of the true pelvis and, after a course of some three inches, joins the *internal iliac* (fig. 5, I.I.) which drains the pelvis and so forms the *common iliac vein*. In front of the body of the fifth lumbar vertebra the common iliac veins of the two sides unite to form the *inferior vena cava* (fig. 5, I.V.C.), a very large trunk which runs up on the right of the abdominal aorta to an opening in the diaphragm (*q.v.*). On its way it receives spermatic or ovarian veins from the genital glands, *renal veins* (fig. 5, R.V.) from the kidneys, and *lumbar veins* (fig. 5, L.V.) from the abdominal walls. Before reaching the diaphragm it lies in a groove in the back of the liver (*q.v.*) and receives the *hepatic veins* from that organ. The hepatic portal system which lies in the abdomen will be treated later.

Veins of the Thorax.—The inferior vena cava, after piercing the diaphragm, has a very short thoracic course and opens into the lower and back part of the right auricle of the heart (*q.v.*). The *right* and *left innominate veins* (fig. 5, R.I. and L.I.) are formed behind the sternal end of the clavicle by the union of the subclavian and internal jugulars of their own side. The left vein is much longer than the right and runs nearly horizontally behind the upper half of the manubrium sterni to join its fellow on the right side of that bone just below the first rib. By the junction of these the *superior vena cava* (fig. 5, S.V.C.) is formed, which runs down to the right auricle of the heart. The chief tributaries of the innominate veins are the *vertebral*, the *internal mammary* and the *inferior thyroid*.

The intercostal veins open into the *azygos veins*, which begin in the abdomen sometimes by a vertical trunk joining the lumbar veins known as the *ascending lumbar*, sometimes on the right side by a communication with the inferior vena cava. The right azygos vein is known as the *vena azygos major* (fig. 5, A.M.) and passes through the aortic opening of the diaphragm. Entering the thorax, it runs up in front of the thoracic vertebrae, to the right of the aorta and thoracic duct, and receives the intercostal veins of the right side. At the level of the fourth thoracic vertebra it arches forward to open into the posterior surface of the superior vena cava.

On the left side, the upper intercostal veins join to form the left superior intercostal vein (fig. 5, L.S.I.), which opens into the left innominate. Lower down the intercostal veins from the fourth to the seventh spaces form the *superior hemiazygos vein* or hemiazygos accessoria (fig. 5, H.A.), which runs down on the left of the spinal column and, crossing it about the level of the eighth or ninth thoracic vertebra, opens into the vena azygos major. The lower intercostal veins on the left side join the *inferior hemiazygos vein* (fig. 5, H.V.), which runs up and opens either into the superior hemiazygos or into the azygos major below the opening of that vein.

Pulmonary Venous System.—The veins emerging from the lungs bring back the oxygenated blood from those organs to the left ventricle of the heart and also the greater part, if not all, of the blood carried by the bronchial arteries to nourish the lungs. The existence of bronchial veins is asserted, but they are extremely difficult to demonstrate, and if present are quite incapable of returning all the blood which the bronchial arteries carry to the lungs. There are three pulmonary veins coming out of the right lung, while on the left there are only two. On the right side, however, two of the three veins usually unite in the root of the lung, so that there are, as a rule two pulmonary veins entering the left auricle of the heart on each side, but it is not uncommon to find three on the right side or one on the left. The pulmonary veins have no valves and return the blood carried to the lungs by the pulmonary arteries as well as most, if not all, of that carried by the bronchial arteries.

Hepatic Portal System.—The veins which drain the blood from the stomach, intestines, spleen and pancreas unite to form a large vein which begins behind the head of the pancreas and ends by dividing into right and left branches in the transverse fissure of the liver. This is the *portal vein* which lies in front of the inferior vena cava and is about three inches long. Its formative tributaries are the *superior* and *inferior mesenteric* and the *splenic veins*. These accompany the arteries of the same name, and their most usual method of termination is that the inferior mesenteric runs up and joins the splenic to the left of the middle line of the body, and this, after running horizontally to a point a little to the right of the middle line, joins the superior mesenteric, and so the portal vein is formed. There are two marked characteristics of the portal system; one is that it has no valves and the other that it begins and ends in capillaries, since the two terminal branches of the portal vein branch and rebranch in a manner already described in the article LIVER. In the lower part of the rectum the veins run partly into the portal and partly into the general system, and in this dependent position they are liable to become varicose and to form haemorrhoids or piles.

The histology of the veins corresponds very closely to that of the arteries (*q.v.*); their walls are, however, much thinner and there is less muscular and elastic tissue. At certain places, especially where tributaries come in, the endothelial lining is raised to form semilunar pocket-like valves. In most cases there are two cusps to each valve, but three or one are sometimes found. The opening of the pocket is of course arranged so that it shall only be filled when there is a tendency to regurgitation of the blood.

Embryology.

The *vitelline* or *omphalo-mesenteric veins*, returning the blood from the yolk sac, are the first to appear, and later on, with the formation of the placenta, the umbilical veins develop. Both these open into the hinder (caudal) part of the heart, which is already being constricted off as the *sinus venosus* (see fig. 1).

While this is going on the veins from the different body segments are received into two longitudinal trunks on each side, the anterior (cephalic) of which is the *primitive jugular* or anterior cardinal (fig. 1, P.J.), and the posterior (caudal), the *posterior cardinal* or simply *cardinal vein* (fig. 1, P.C.). As the heart is at first situated in the region which will later be the neck of the embryo, the primitive jugular receives very few segmental veins and the cardinal very many. These two trunks join one another on each side and open into the side of the *sinus venosus* (S.V.) by a transverse communication which is called the *duct of Cuvier* (D.C.). The condition of the venous system at this stage is shown in the accompanying diagram (fig. 1).

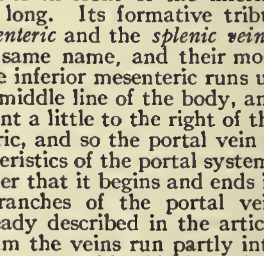

FIG. 1.

As the vitelline veins run from the yolk sac to the heart along each side of the primitive fore-gut they pick up the mesenteric veins from the intestines as well as the splenic and pancreatic veins as soon as these viscera are formed. The liver, however, is developed right across their path, and both they and the umbilical veins break up into a mass of capillaries in it; leaving that part of them which lies between the liver and the heart to form the primitive hepatic veins (fig. 2, H.V.). While the vitelline veins are lying on each side of the fore-gut (future duodenum) they are connected by three transverse channels, the anterior and posterior of which appear on the ventral side of the gut, the middle on the dorsal side (see fig. 2).

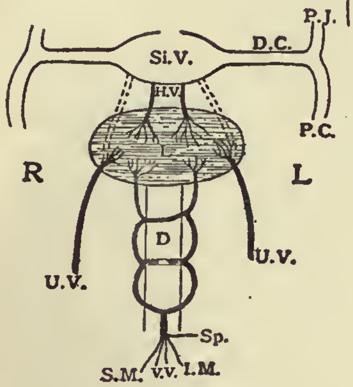

FIG. 2.

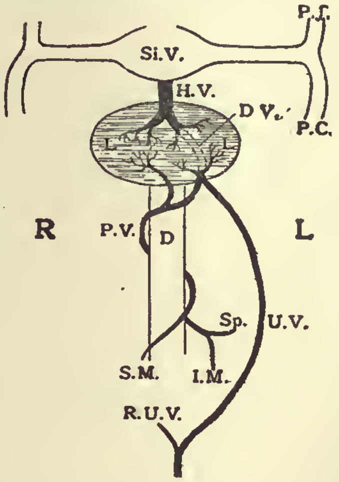

FIG. 3.

This figure of eight does not persist, however, because the anterior (cephalic) part of it on the left and the posterior (caudal) part on the right become obliterated, and what is left forms the *portal vein* (fig. 3, P.V.). The two umbilical veins unite at the umbilicus (fig. 3) and soon all the blood from the placenta passes through the left one, the right becoming rudimentary.

The left umbilical vein on reaching the liver now joins the left branch of the portal vein and establishes a new communication with the left hepatic vein. This is the *ductus venosus* (fig. 3, D.V.), and, as soon as it is formed, there is no longer any need that all the blood returning from the placenta should pass through the liver capillaries. The development of the cardinal veins must now be returned to. As the heart moves from the neck into the thorax the primitive jugulars elongate and it is now recognized become the internal jugulars in the greater part of their extent. When the arms begin to bud out subclavian veins are developed (fig. 4, S.) and an oblique connecting vein (figs. 4 and 5, L.I.) is established

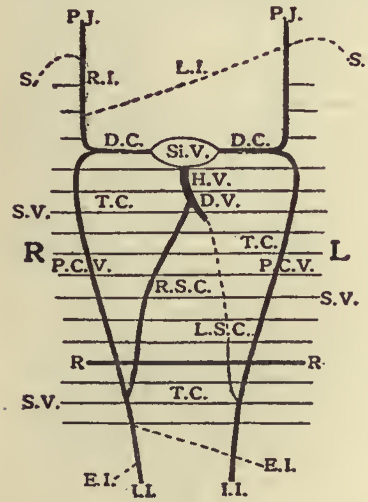

FIG. 4.

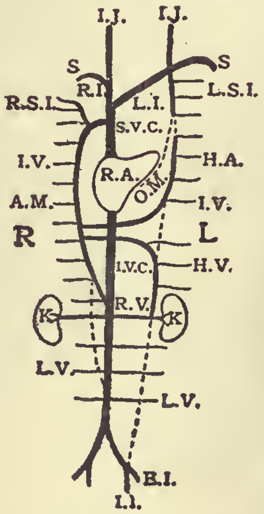

FIG. 5.

between the point of junction of the left subclavian with the primitive jugular and the hinder part of the primitive jugular of the right side. This connexion becomes the left innominate vein, while the hinder part of the primitive jugular persists as the *left superior intercostal vein* (fig. 5, L.S.I.). On the right side that part of the primitive jugular between the subclavian and the junction with the left innominate becomes the right innominate (figs. 4 and 5, R.I.) while the hinder (caudal) part of the right primitive jugular and the right duct of Cuvier become the superior vena cava (figs. 4 and 5, S.V.C.). The external jugular is a later formation. The right and left posterior cardinal veins receive the intercostal and lumbar segmental veins and are continued into the lower limbs as the internal iliac and eventually the sciatic veins (figs. 4 and 5, I.I.), the primitive bloodpath from the thighs. The veins from the primitive kidneys open into the segmental veins, and when the permanent kidney is formed (see URINARY SYSTEM) a large *renal vein* on each side is established. There are, however, many cross communications (fig. 4, T.C.) between the right and left posterior cardinal veins, some of which become very important later on, though most of them are transitory. The probable origin of the *inferior vena cava* is to be sought in a pair of veins called *subcardinals* which have been found in the rabbit embryo lying parallel and a little ventral to the posterior cardinals (fig. 4, R.S.C.–L.S.C.) and effecting a junction with the renals and transverse communications (T.C.) as they cross these. Posteriorly (caudal) they join the cardinals, but anteriorly the right one establishes a communication with the ductus venosus (fig. 4, D.V.) a little below the point at which that vessel joins the left hepatic. It is from the right one of these that the greater part of the inferior vena cava is formed. It will now be seen that the adult vena cava is formed by contributions from four embryonic veins, most anteriorly the hepatic, then the ductus venosus, then the right subcardinal and posteriorly the right posterior cardinal (F. T. Lewis, *Am. J. of Anat.* vol. 1, 229, 1902). The anterior (cephalic) part of the right posterior cardinal forms the *vena azygos major*, and an inspection of fig. 4 will show that in the adult this may rise from the renal, from an ascending lumbar vein or, by a cross communication above the renal, from the inferior vena cava. The left posterior cardinal becomes obliterated below and its segmental tributaries find their way by cross communications to the vena cava (fig. 5). Above (cephalad) the left renal vein the left cardinal forms the hemiazygos (fig. 5, H.V.) and, higher still, the hemiazygos accessoria (fig. 5, H.A.). These open into the azygos major by persistent cross communications which lie dorsal to the heart when that organ reaches its permanent position. It must be mentioned in this connexion that some modern authorities doubt whether the azygos veins of mammals are really persistent cardinals except quite in their anterior parts, just before they join the ducts of Cuvier. The left duct of Cuvier is only represented in the human adult by the oblique vein of Marshall on the dorsum of the left auricle. The external iliac veins (figs. 4 and 5, E.I.) become fully developed, like their arteries, when the blood changes its course from the back to the front of the thigh. After birth the umbilical vein and the ductus venosus become converted into fibrous cords and the circulation in the pulmonary veins is established. (For further details see *Development of the Human Body*, by J. P. McMurrich, London, 1906. In this will be found the literature of the subject up to that date, the writings of F. Hochstetter being the most important. See also Quain's *Anat.* vol. i., 1908.)

Comparative Anatomy.

In the Acrania (*Amphioxus*), although there is no heart, the blood vessels returning the blood to the subpharyngeal region are distinctly of a vertebrate type. There is a subintestinal vessel or vein bringing the blood from the intestine to the liver and breaking up into capillaries in that organ just as the portal vein does in the higher forms. From the liver a hepatic vein carries the blood forward to the region below the pharynx where the heart is formed in Vertebrata. There is no renal portal system. In the Cyclostomata (lampreys and hags) the cardinal veins are formed and the blood from the caudal vein passes directly into the posterior cardinals without any renal portal system. In fishes the single caudal vein divides into two branches, each of which runs forward to the outer side of its respective kidney and ends by giving numerous branches to that viscus. The blood returning from the kidney passes into the beginning of its own posterior cardinal vein or sinus, which lies on the inner side of the kidney. This constitutes a *renal portal system.* The cardinal veins and ducts of Cuvier closely resemble the arrangement already detailed in the human foetus, while the hepatic portal system from the intestine to the liver is constant in this and all other vertebrates.

In the Dipnoi (mud-fish) a pulmonary vein from the lung-like swim-bladder is formed and an inferior vena cava or postcaval vein carries the blood from the kidneys to the heart. This is its first appearance in the vertebrate phylum. In the lower fishes there is a vein of the lateral line on each side, but in the Dipnoi these coalesce and form a median anterior (ventral) abdominal vein which is constant in the Amphibia. Subclavian and iliac veins return the blood from the fins and open respectively into the junction of the anterior and posterior cardinals and into the caudal vein.

In the tailed Amphibia (*Urodela*) the postcaval and posterior cardinal veins are well developed, the former vessel running from the right cardinal vein a little in front of (cephalad) the kidney to the hepatic vein, in this way closely foreshadowing man's embryology. In the Anura (frogs and toads) the posterior cardinals are usually suppressed, but these are very specialized animals. The anterior abdominal vein in amphibians joins the portal vein close to the liver.

In the Reptilia the renal portal circulation persists, but is rudimentary in birds and disappears in mammals. The anterior abdominal or epigastric vein of amphibians and reptiles returns the blood from the allantois in the embryo and in higher forms becomes the umbilical veins returning the blood from the placenta; there is, therefore, a continuous line of ascent from the lateral line veins of the fish to the umbilical vein of man. In reptiles, birds, monotremes, marsupials and many rodents, insectivores, bats and ungulates, a left superior vena cava (precaval vein) is present as well as a right; it passes ventral to the root of the left lung and then dorsal to the left auricle of the heart until it reaches the coronary sinus to open into the right auricle. Its course is indicated in man by the left superior intercostal vein, the vestigial fold of Marshall (see COELOM AND SEROUS MEMBRANES) and the oblique vein of Marshall. It can be readily reconstructed from figs. 4 and 5 if the transverse communication (L.I.) is obliterated. In some mammals the post-caval vein is double, especially in its hinder (caudal) part, and this sometimes occurs as a human abnormality (see F. W. McClure, *Am. Journ. of Anat.* vol. 2, 1903, and vol. 5, 1906, also *Anat. Anzeiger*, Bd. 29, 1906).

Except in Cetacea, one or both azygos veins are always present in mammals. When there is only one it is usually the right, though a few forms among the marsupials, rodents and ungulates have only the left (F. E. Beddard, *P.Z.S.*, 1907, p. 181). In many of the lower mammals the external jugular vein is much larger than the internal and returns most of the blood from the brain through an opening called the postglenoid foramen. For this reason it was formerly regarded as the representative of the primitive jugular. It is now, however, thought that the internal jugular is that representative, and that the arrangement of man, in which the internal jugular drains the interior of the cranium, is the more generalized and primitive.

For further details and literature see R. Wiedersheim's *Comparative Anatomy of Vertebrates*, translated by W. N. Parker (London, 1907). (F. G. P.)

VEINS, in geology, masses of rock which occupy fissures in other rocks. They may have originated in many different ways and present a great variety of forms and structures. We may classify them in three groups: (i.) veins of igneous rock, (ii.) of sedimentary, and (iii.) of minerals deposited by water or by gases.

Veins of igneous rock are practically the same as dikes; yet a distinction is sometimes made that dikes are narrow, often straight-walled and run for considerable distances, while veins are irregular, discontinuous and of limited extent. Where granite invades sedimentary or metamorphic rocks it very commonly emits vast numbers of dikes. The margin of the granite is full of blocks of all sizes, so that it is often impossible to say where the solid granite ends and the fringe of veins begins. An intrusion plexus of this sort seldom extends for more than a few hundred yards; many granites, on the other hand, have sharp and well-defined margins and send few veins into the country rock.

In plutonic rock areas veining is also very common. Great intrusive masses have not as a rule been injected in one stage but have been slowly enlarged by gradual or repeated inflows, and often the earliest portions had consolidated before the last were introduced. Very frequently the older rocks are of a different character, being usually more basic than those which succeed them, and this makes the veining more obvious. For instance, it is common to find peridotite traversed by many veins of gabbro, or diorite injected with numerous veins of granite, though in either case the rocks are part of one plutonic boss or laccolite. The crystalline structure of the vein-rock and the surrounding mass is usually quite similar and there may be no fine-grained edges to the veins; these facts establish that the older mass though solid had not yet cooled down, so that the veining is directly connected with the injection process and the two rocks have been derived from the same source, but one is slightly later than the other.

Among the Laurentian or Lewisian gneisses, which resemble granites, diorites and gabbros in composition, but have a banded or foliated structure, veining of this type is almost universal. The veins are of all sizes and of very irregular shape. Frequently they run along the foliation of the gneiss, but often also they cross it obliquely or at right angles. Such gneisses were produced by the injection of a partly differentiated and consequently non-homogeneous magma, by successive stages, under a rock crust which was in movement or was subjected to intermittent pressures during consolidation.

In certain cases the new material introduced into the rock by these veins bulks almost as largely as the original substance. A shale, slate or phyllite is sometimes so filled with threads of granite that its composition and appearance are completely altered. Thin pale threads of quartz and felspar, not more than a tenth of an inch in thickness may be seen following the bedding planes, or the cleavage and sometimes also the slip-cleavage. The distance between the veins may be no greater than the breadth of the veins themselves, and thus a striped or banded rock is produced, resembling a gniess but of dual origin, a mixed rock which is described properly as a "composite" or "synthetic" gneiss. The French geologists who first insisted on the importance of this group of rocks have called the process *lit par lit* (bed-by-bed) injection. The best examples of this in Britain are to be found around the granites of Mull and northern Sutherlandshire. The rocks invaded by granite in this manner often show intense contact alteration and are to a large extent recrystallized.

The short irregular veins which commonly occur within areas of granite, diorite, gabbro and other plutonic rocks are often much more coarsely crystalline than the rock around them. This is no doubt partly due to the high temperature of the whole complex and to slow crystallization, but it may also be ascribed to the action of vapours dissolved in the magma and gradually released as it solidifies. Such coarse-grained igneous rocks are called pegmatites (*q.v.*). It is clear that they are not purely igneous but are partly pneumatolytic.

With the pegmatites we may class the fine-grained acid veins (aplites) which are found not only in granites but also in many diabases. They occur in irregular streaks or as long branching well-defined veins, and are usually more rich in quartz and felspar than the surrounding rock. Formerly they were often described as contemporaneous or as segregation veins; but no vein can be in strict accuracy contemporaneous with the rock which it intersects, and many of them give evidence of having been intruded into their present situation, since their minerals are so arranged as to show flexion structure. But they are always intimately connected, as their mineral composition indicates, with the rock mass in which they lie, and they represent merely the last part of the magma to consolidate. The fissures they occupy are presumably due to contraction, seeing that they are not accompanied by displacement, brecciation or faulting.

Veins of sedimentary rock are few and of little importance. They occur where sediment has gathered in cavities of other rocks. Lava streams, for example, when they cool become split up into irregular blocks, and in the crevices between these ashes, sand and clay will settle. Submarine lavas are often traversed by great numbers of thin veins of sandstone, and a similar phenomenon may also be noted in the tuff of submarine necks or other ash beds. Cracks in limestone and dolomite are widened by the solvent action of percolating waters and may be filled with gravel, soil, clay and sand. In the Carboniferous Limestone, for instance, veins of bedded sandstone sometimes pass down from overlying Triassic deposits. The upper surface of the chalk in the south of England has frequently many deep funnel-shaped pipes which are occupied by Tertiary or recent accumulations.

The third group of veins, namely, those which have been filled by deposits from solution in water or in vapours, is of the greatest importance as including a very large number of mineral veins and ore-bodies. They are also the source of the great majority of the finely crystallized specimens of minerals.

The deposition of minerals on the walls of fissures by a process of sublimation may be observed at any active volcano. The cracks in the upper part of lava flows are often lined by crystals of sal-ammoniac, sodium chloride, ferric chloride and other volatile substances. By oxidation of the iron chloride bright scales of haematite (ferric oxide) arise; sulphurous acid and sulphuretted hydrogen, given out as gases, react on one another, producing yellow encrustations of sulphur; and copper oxide (tenorite) and a great variety of other minerals (alum, iron sulphate, realgar, borates and fluoride) are found about fumaroles of Vesuvius and other volcanoes.

Most veins, however, are not of superficial origin but have been formed at some depth. The heat given out by masses of rocks which were injected in a molten state is no doubt sufficiently high to volatilize many minerals. The pressure, however, also must be taken into account, as it tends to retain these substances in a liquid condition. Water vapour is always the most abundant gas in a volcanic magma, and next to it are carbonic acid, sulphurous acid, sulphuretted hydrogen and hydrochloric acid. The physical condition of the substances passing outwards from an igneous mass through fissures in the superincumbent rocks will depend on the nature of the substances, on the temperature and the pressure. Near the granite the heat is so great, at first at any rate, that gaseous materials must greatly preponderate; but farther away many of them will be condensed and hot aqueous solutions of complex composition will fill the cracks.

Veins deposited by the action of gases and vapours are said to be of "pneumatolytic" origin; where hot aqueous solutions have been the principal agency in their formation they are "hydatogenetic." It is often very difficult to ascertain to which of these classes a mineral vein belongs, especially as we are in ignorance of the behaviour of many substances at high temperatures and under great pressures.

The veins which yield tin-ores in Cornwall and in most other tin-producing countries are generally regarded as typical pneumatolytic deposits. Tin forms a volatile fluoride which may be decomposed by water, forming tin oxide, the fluorine passing into hydrofluoric acid which may act as a catalytic agent or carrier by again combining with tin. Around tin-bearing veins and in the material which fills them there are usually many minerals containing fluorine, such as topaz, fluor-spar and white mica. Some borates too are volatile at high temperatures, and minerals containing boron (especially tourmaline) are very common in tin veins. Also since ore deposits of this character are found nearly invariably in granite or in the rocks which have been invaded by granite there is good reason to hold that fluoric and boric gases were important agents in the production of tin veins. It is not necessary, however, to believe that all the materials which are found in these veins were introduced as vapours, for as the temperature sank currents of hot water would follow which would fill up any cavities.

The tin veins of Cornwall often contain copper ores in their upper parts and at greater distances from the granite, a fact which indicates that the copper salts were deposited from solution at lower temperatures than the tin ores. A very large number of important ore deposits have been laid down by hot waters emanating from deep-seated intrusive masses. Nearly all the principal goldfields (except gravels or placers) are in districts where igneous dikes, veins and sills abound, and it is often perfectly clear that the introduction of the gold ores is intimately connected with the intrusive masses. The Witwatersrand deposits, although by many considered to be old auriferous gravel, have been regarded as owing their value to gold deposited from vapours emanating from certain of the dikes which traverse the banket rock or conglomerate. The importance of these hot ascending currents of water, proceeding from eruptive magmas, has been fully recognized, and is now probably the most widely accepted theory of the genesis of mineral veins.

The water falling on the earth's surface will to a large extent percolate downwards into the rocks, and it will dissolve mineral matters, especially at the greater depths, owing to the increased temperature and pressure; conversely, as it ascends it will lay down deposits or veins. This is the theory of "lateral secretion," at one time in great favour, but now regarded as of less importance. Ferruginous waters on passing through limestone rocks may deposit their iron as haematite or siderite, removing a proportionate amount of lime, and in this way great bodies of ironstone have been formed, as in Cumberland and Yorkshire, partly along the bedding of the limestone but also in veins, pockets and irregular masses. Many lead and zinc veins probably belong also to this class. By analysis it has been proved that in nearly all the common rocks there exist very minute quantities of such metals as gold, silver, lead, copper, zinc. If these can be extracted in solution in water they might conceivably be deposited subsequently in fissures in the rocks.

Controversy has raged between opposing schools of geologists, one considering that most mineral veins owe their existence to currents of hot water ascending from deep-seated igneous rocks, and the other that the metals were derived from the country rocks of the veins and were extracted from them by cold descending currents of water. There are cases which can be explained on one of these hypotheses only, and sufficiently establish that both of them are valid; but the general opinion at the present time is in favour of the first of these explanations as the most general.

The fissures in which veins have been deposited owe their origin to a variety of causes. Many of them are lines of fault, the walls of which have been displaced before the introduction of the vein minerals. Others seem to be of the same nature as joints, and are due either to contraction of the rocks on solidification, to folding or to earthquake shocks. In the vicinity of intrusive masses many fissures have been produced by the contraction of rock masses which had been greatly heated and then slowly cooled. Veins often occur in groups or systems, which have a parallel trend and may sometimes be followed for many miles. The larger veins may branch and the branches sometimes unite after a time, enclosing masses of country rock or "horses." Cross-courses are fissures which intersect the lodes; they are often barren, and at other times carry an entirely different suite of minerals from those of the mineral veins. A peculiar group of veins has been described from the Bendigo district of Australia; they are saddle-shaped and in transverse section resemble an inverted U. The beds in which they occur are folded sharply into arches and troughs, and in folding they have separated at the crests of the arches, leaving hollows which were subsequently filled up with ore.

The minerals occurring in the veins are sometimes classified as "ores" and "gangue": the former being those which are of value while the others are unprofitable. The commonest of the gangue minerals are quartz, calcite, barytes and fluor-spar. Usually a large number of minerals occurs in each vein, and the natural association or "paragenesis" of certain minerals which frequently are found together is a practical guide of much value to the engineer and prospector. A definite sequence in the order of deposit of the constituent minerals can often be recognized, the earlier being situated on the walls of the fissures or enclosed and surrounded by the later, and the microscopic study of veinstone shows that they have often a complicated history.

Many types of structure are met with in veinstones and vein deposits. Some are structureless, homogeneous or massive, like the quartz veins which are often found in districts composed of slate or phyllite. Others are banded, with sheets of deposit, each consisting of one mineral, usually parallel to the walls of the lode. These veins are often symmetrical, with corresponding layers following one another inwards from the walls on each side.

The veinstones are frequently crushed either by faulting or by irregular movements of the walls, and in such cases the veinstones have a shattered or brecciated appearance. If the crushing took place while the ore deposits were still being introduced, the broken rock is often cemented together into a compact mass. Rounded masses of rock or of veinstone are often met with, looking exactly like pebbles, but they are analogous to crush-conglomerates, as the fragments have been shaped by the movements of the walls of the vein. Frequently these movements have reopened a fissure which had been filled up, and a new vein is subsequently formed alongside of the old one; this process may be repeated several times.

The mineral-bearing solutions may exert a powerful influence on the walls of the veins, removing certain constituents and depositing others; in this way the walls of the vein become ill defined. The commonest change of this kind is silicification, and rocks of many different kinds, such as slate, limestone, andesite and felsite, are often completely replaced by quartz in the vicinity of mineral veins which have a quartzose gangue. Tin veins in granite and slate may be surrounded by a zone of rock which has been impregnated with cassiterite and is worth working for the metal. These changes are of a "metasomatic" type, involving replacement of the original rock-substance by introduced materials. Many of the best examples of this are furnished by limestone, which is one of the rocks most easily affected by percolating solutions.

The distinction between mineral veins and other veins is to a large extent artificial. With improvement of methods of mining and extraction deposits formerly unprofitable become payable, and in all cases veins vary considerably in the amount of ore they carry. The rich parts are sometimes called shoots or bonanzas, while the barren portions are often left standing in the mine. Near the ground surface the veinstones become oxidized and the metallic minerals are represented by oxides, carbonates, hydrates, or in the case of gold and silver veins they may be rich in the metals themselves. Below the zone where oxidizing surface-waters percolate a different series of minerals occurs, such as sulphides, arsenides and tellurides. If the ores are insoluble they will tend to be concentrated in the upper part of the vein rock, which may be greatly enriched in this way. Pyritic veins are changed to rusty-looking masses, "gossans," owing to the oxidation of the iron at the surface. Though instances are known of veins which come to an end when followed downwards, it seems probable that the majority of veins descend to great depths, and there is little reason to believe that they become less rich in the heavy metals. (J. S. F.)

VEIT, PHILIPP (1793–1877), German painter, one of the leaders of the German romantic school, was born in Berlin. Having received his first art education in Dresden and Vienna, he was strongly influenced by, and joined the group of, the Nazarenes in Rome, where he worked for some years before taking up his abode in Frankfort. In this city, where his most important works are preserved at the Staedel Institute, he was active from 1830 to 1843, as director of the art collections and as professor of painting. From 1853 to his death in 1877 he held the post of director of the municipal gallery at Mayence. Like his fellow-Nazarenes he was more draughtsman than painter, and though his sense of colour was stronger than that of Overbeck or Cornelius, his works are generally more of the nature of coloured cartoons than of paintings in the modern sense. His principal work is the large fresco of "The Introduction of Christianity into Germany by St Boniface," at the Staedel Institute in Frankfort. In the cathedral of that city is his "Assumption," whilst the Berlin National Gallery has his painting of "The Two Marys at the Sepulchre." To Veit is due the credit of having been the first to revive the almost forgotten technique of fresco painting.

See *Kunst, Künstler und Kunstwerke*, by Valentin Veit.

VEITCH, JOHN (1829–1894), Scottish poet, philosopher, and historian of the Scottish border, son of a Peninsular veteran, was born at Peebles on the 24th of October 1829, and educated at Edinburgh University. He was assistant lecturer successively to Sir William Hamilton and A. Campbell Fraser (1856–60). In 1860 he was appointed to the chair of logic, metaphysics and rhetoric at St Andrews, and in 1864 to the corresponding chair at Glasgow. In philosophy an intuitionist, he dismissed the idealist arguments with some abruptness, and thereby lost much of the influence gained by the force of his personal character. He died on the 3rd of September 1894. He will be remembered chiefly for his work on Border literature and antiquities.

He published translations of Descartes' *Discours de la méthode* (1850) and *Méditationes* (1852); an edition of Sir W. Hamilton's lectures with memoir (1869, in collaboration with H. L. Mansel); *Tweed, and other Poems* (1875); *History and Poetry of the Scottish Border* (1877; ed. 1893); *Institutes of Logic* (1885); *Knowing and Being* (1889); *Merlin* (1889); *Dualism and Monism* (1895); *Border Essays* (1896). See *Memoir* by his niece, Mary R. L. Bryce (1896).

VEJÉR DE LA FRONTERA, a town of southern Spain, in the province of Cadiz, on the right bank of the river Barbate and on the Cadiz-Tarifa railway. Pop. (1900) 11,298. Vejér de la Frontera occupies a low hill overlooking the Straits of Gibraltar and surrounded by orchards and orange groves. It contains several ancient churches and convents, and the architecture of many of its houses recalls the period of Moorish rule, which lasted from 711 until the town was captured by St Ferdinand of Castile in 1248. Agriculture and fruit-farming are the chief industries; fighting bulls are also bred in the neighbourhood.

VELARIUM, the curtain or awning extended above the auditorium of the Roman theatres and amphitheatres to protect the spectators from sun and rain.

VELAZQUEZ, DIEGO RODRIGUEZ DE SILVA Y (1599–1660), the head of the Spanish school of painting and one of the greatest painters the world has known, was born in Seville early in June 1599, the year in which Van Dyck also first saw the light at Antwerp. His European fame is of comparatively recent origin, dating from the first quarter of the 19th century. Till then his pictures had lain immured in the palaces and museum of Madrid; and from want of popular appreciation they had to a large extent escaped the rapacity of the French marshals during the Peninsular War. In 1828 Sir David Wilkie[1] wrote from Madrid that he felt himself in the presence of a new power in art as he looked at the works of Velazquez, and at the same time found a wonderful affinity between this master and the English school of portrait painters, being specially reminded of the firm, square touch of Raeburn. He was struck by the sense of modernness of impression, of direct contact with nature, and of vital force which pervaded all the work of Velazquez, in landscape as well as in portraiture. Time and criticism have now fully established his reputation as one of the most consummate of painters, and accordingly Ruskin says of him that "everything Velazquez does may be taken as absolutely right by the student." At the present day his marvellous technique and strong individuality have given him a power in European art such as is exercised by no other of the old masters. Although acquainted with all the Italian schools, and the friend of the foremost painters of his day, he was strong enough to withstand every external influence and to work out for himself the development of his own nature and his own principles of art. A realist of the realists, he painted only what he saw; consequently his imagination seems limited. His religious conceptions are of the earth earthy, although some of his works, such as the "Crucifixion" and the "Christ at the Column," are characterized by an intensity of pathos in which he ranks second to no painter. His men and women seem to breathe, his horses are full of action and his dogs of life, so quick and close is his grasp of his subject. England was the first nation to recognize his extraordinary merit, and it owns by far the largest share of his works outside of Spain.[2]

[1] See Cunningham's *Life*, vol. ii.

[2] Of the 274 works attributed to Velazquez by Mr Curtis, 121 are in the United Kingdom, while France has but 13, Austria-Hungary 12, Russia 7, and Germany about the same number. Beruete, who only allows 90 known pictures to be genuine works of Velazquez, allots 14 to the United Kingdom, which number still considerably exceeds that of any other country save Spain.

But Velazquez can only be seen in all his power in the gallery of the Prado at Madrid, where over sixty of his works are preserved, including historical, mythological and religious subjects, as well as landscapes and portraits. It is hardly creditable to the patriotism of Seville, his native town, that no example of his work is to be seen in the gallery of that city. Seville was then in the height of its prosperity, "the pearl of Spain," carrying on a great trade with the New World, and was also a vigorous centre of literature and art. For more than a hundred years it had fostered a native school of painting which ranked high in the Peninsula, and it reckoned among its citizens many whose names are prominent in Spanish literature.

Velazquez was the son of Rodriguez de Silva, a lawyer in Seville, descended from a noble Portuguese family, and was baptized on the 6th of June 1599. Following a common Spanish usage, he is known by his mother's name Velazquez. There has been considerable diversity of opinion as to his full name, but he was known to his contemporaries as Diego de Silva Velazquez, and signed his name thus. He was educated, says Palomino, by his parents in the fear of God, and was intended for a learned profession, for which he received a good training in languages and philosophy. But the bent of the boy was towards art, and he was placed under the elder Herrera, a vigorous painter who disregarded the Italian influence of the early Seville school. From his works in Seville we can see that Herrera was a bold and effective painter; but he was at the same time a man of unruly temper, and his pupils could seldom stay long with him. Velazquez remained but one year—long enough, however, to influence his life. It was probably from Herrera that he learned to use long brushes, or, as J. E. Hodgson, R.A., suggested, brushes with long bristles, by means of which his colours seem to be floated on the canvas by a light, fluent touch, the envy and despair of his successors. From Herrera's studio Velazquez betook himself to a very different master, the learned and pedantic Pacheco, the author of a heavy book on painting, and, as we see by his works at Madrid, a dull, commonplace painter, though at times he could rise to a rare freedom of handling and to a simple, direct realism that is in direct contradiction to the cult of Raphael preached by him in his writing. A portrait by Pacheco, owned by Sir Frederick Cook, which shows this master's full power, was exhibited at Burlington House in 1907. In Pacheco's school Velazquez remained for five years, studying proportion and perspective, and seeing all that was best in the literary and artistic circles of Seville. Here also he fell in love with his master's daughter Juana, whom he married in 1618 with the hearty approval of Pacheco, who praises his hand and heart, claiming at the same time all the credit of having been his master. The young painter set himself to copy the commonest things about him—earthenware jars of the country people, birds, fish, fruit and flowers of the market-place. To paint well and thoroughly what he saw, to model with his brush, and to colour under the influence of light and shade were for him the vital purpose, the first lesson, in his art. It was with deliberate purpose that Velazquez painted these *bodegones* (tavern-pieces), as they were called; for we are told that he said he would rather be the first painter of common things than the second in higher art. Carrying out this idea still further, Velazquez felt that to master the subtlety of the human face he must make this a special study, and he accordingly engaged a peasant lad to be his servant and model, making innumerable studies in charcoal and chalk, and catching his every expression. We see this model, probably, in the laughing boy of the Hermitage "Breakfast," or in the youngest of the "Musicians" acquired for the Berlin Museum in 1906. In such work as this, and in his studies by the wayside, Velazquez laid the foundation of his subsequent mastery of expression, of penetration into character, and of rendering the life of his sitter to the quick. He saw the world around him teeming with life and objects interesting to the painter, and he set himself to render these. His manner is as national as that of Cervantes. He lived and died racy of the soil. The position and reputation of Velazquez were now assured at Seville. There his wife bore him two daughters—all his family so far as is known. The younger died in infancy, while the elder, Francisca, in due time married Bautista del Mazo, a painter, whose large family is that which is represented in the important picture in Vienna which was at one time called the "Family of Velazquez." This picture is now by common consent given to Mazo. In the gallery at Madrid there is a portrait of Juana, his wife, holding a drawing-tablet on her knee. There was formerly in the possession of Lord Dudley another portrait of his wife by Velazquez, painted, perhaps, in the first year of their happy marriage. Of this early Seville manner we have an excellent example in "El Aguador" (the Water-Carrier) at Apsley House (London). Firm almost to hardness, it displays close study of nature. One can see in it the youthful struggle to portray the effects of light stealing here and there over the prominent features of the face, groping after the effects which the painter was to master later on. The brushwork is bold and broad, and the outlines firmly marked. As is usual with Velazquez at this time, the harmony of colours is red, brown and yellow, reminding one of Ribera. For sacred subjects we may turn to the "Adoration of the Magi" at Madrid, dated 1619, and the "Christ and the Pilgrims of Emmaus" in the collection of Don Manuel de Soto in Zurich, in both of which we have excellent examples of his realism. In the "St John in the Desert" we again find his peasant boy transformed into the saint.

But Velazquez was now eager to see more of the world. Madrid, with its fine Titians, held out strong inducements. Accordingly, in 1622, fortified with letters of introduction to Fonseca, who held a good position at court, he spent some months there, accompanied only by his servant. Here he painted the portrait of the poet Gongora, a commission from Pacheco, but the picture known by that name in the gallery at Madrid cannot with certainty be identified as Velazquez's portrait; it is more probably by Zurbaran. The impression which Velazquez made in the capital must have been very strong, for in the following year he was summoned to return by Olivares, the all-powerful minister of Philip IV., fifty ducats being allowed to defray his expenses. On this occasion he was accompanied by his father-in-law. Next year (1624) he received from the king three hundred ducats to pay the cost of the removal of his family to Madrid, which became his home for the remainder of his life. Weak and worthless as a king, Philip had inherited the art-loving propensities of his race, and was proud to be considered a poet and a painter. It is one of the best features of his character that he remained for a period of thirty-six years the faithful and attached friend of Velazquez, whose merit he soon recognized, declaring that no other painter should ever paint his portrait. By his equestrian portrait of the king, painted in 1623, Velazquez secured admission to the royal service with a salary of twenty ducats per month, besides medical attendance, lodgings and payment for the pictures he might paint. The portrait was exhibited on the steps of San Felipe, and was received with enthusiasm, being vaunted by poets, among them Pacheco. It has unfortunately disappeared, having probably perished in one of the numerous fires which occurred in the royal palaces. The Prado, however, has two portraits of the king (Nos. 1070 and 1071) in which the harshness of the Seville period has disappeared and the tones are more delicate. The modelling is firm, recalling that of Antonio Mor, the Dutch portrait painter of Philip II., who exercised a considerable influence on the Spanish school. In the same year the prince of Wales (afterwards Charles I.) arrived at the court of Spain. We are told that he sat to Velazquez, but the picture has disappeared.[1]

In 1628 Rubens visited Madrid on a diplomatic mission for nine months, and Velazquez was appointed by the king to be his guide among the art treasures of Spain. Rubens was then at the height of his fame, and had undertaken as a commission from Olivares the large pictures which now adorn the great hall in Grosvenor House (London). These months might have been a new turning-point in the career of a weaker man than Velazquez, for Rubens added to his brilliant style as a painter the manner of a fascinating courtier. Rubens had a high opinion of the talent of Velazquez, as is attested by Fuensalida, but he effected no change in the style of the strong Spaniard. He impressed him, however, with the desire to see Italy and the works of her mighty painters. In 1627 the king had given for competition among the painters of Spain the subject of the Expulsion of the Moors. Velazquez bore off the palm; but his picture was destroyed in a fire at the palace in 1734. Palomino, however, describes it. Philip III. points with his baton to a crowd of men and women driven off under charge of soldiers, while Spain, a majestic female, sits looking calmly on. The triumph of Velazquez was rewarded by his being appointed gentleman usher. To this was shortly afterwards added a daily allowance of twelve reals, the same amount as was allowed to the court barbers, and ninety ducats a year for dress, which was also paid to the dwarfs, buffoons and players about the king's person—truly a curious estimate of talent at the court of Spain. As an extra payment he received (though it was not paid for five years) one hundred ducats for the picture of Bacchus, painted in 1629 (No. 1058 of the Madrid gallery). The spirit and aim of this work are better understood from its Spanish name, "Los Borrachos" or "Los Bebedores" (the Topers), who are paying mock homage to a half-naked ivy-crowned young man seated on a wine barrel. It is like a story by Cervantes, and is brimful of jovial humour. One can easily see in this picture of national manners how Velazquez had reaped the benefit of his close study of peasant life. The painting is firm and solid, and the light and shade are more deftly handled than in former works. Altogether, this production may be taken as the most advanced example of the first style of Velazquez. It is usual to divide his artistic career by his two visits to Italy, his second style following the first visit and his third the second. Roughly speaking, this somewhat arbitrary division may be accepted, though it will not always apply, for, as is usual in the case of many great painters, his styles at times overlap each other. Velazquez rarely signed his pictures, and the royal archives give the dates of only his more important works. Internal evidence and history, as regards his portraits, supply to a certain extent the rest.

In 1629 Philip gave Velazquez permission to carry out his desire of visiting Italy, without loss of salary, making him besides a present of four hundred ducats, to which Olivares added two hundred. He sailed from Barcelona in August in the company of the marquis de Spinola, the conqueror of Breda, then on his way to take command of the Spanish troops at Milan. It was during this voyage that Velazquez must have heard the details of the surrender of Breda from the lips of the victor, and he must have sketched his fine head, known to us also by the portrait by Van Dyck. But the great picture was not painted till many years later, for Spinola had fallen into disfavour at court. In Venice Velazquez made copies of the "Crucifixion" and the "Last Supper" of Tintoretto, which he sent to the king, and in Rome he copied Michelangelo and Raphael, lodging in the Villa Medici till fever compelled him to remove into the city. Here he painted the "Forge of Vulcan" (No. 1059 of the Madrid gallery), in which Apollo narrates to the astonished Vulcan, a village blacksmith, the news of the infidelity of Venus, while four Cyclops listen to the scandal. The mythological treatment is similar to that of the "Bacchus": it is realistic and Spanish to the last degree, giving a picture of the interior of an Andalusian smithy, with Apollo thrown in to make the story tell. The conception is commonplace, yet the impression it produces is undoubted from the vividness of the representation and the power of expression. The modelling of the half-naked figures is excellent. Altogether this picture is much superior to the other work painted at the same time, "Joseph's Coat," which now hangs in the Escorial. Both these works are evidently painted from the same models.

[1] In 1847 Mr John Snare of Reading exhibited a picture which had come from the sale of Lord Fife in 1809, and which he maintained to be the long-lost work. This led to much controversy; but the claim was rejected by experts, and the picture is said to be now in America.

In looking at these two pictures the spectator is especially struck by the fact that they betray no trace of the influence of the Italians. Velazquez remained true to himself. At Rome he also painted the two beautiful landscapes of the gardens of the Villa Medici, now in the Madrid museum (1106 and 1107), full of sparkle and charm. Landscape as an expression of art never had attraction for the Spaniards; but Velazquez here shows how great a master he was in this branch. The silvery views of Aranjuez, which at one time passed under his name, are now considered to be the work of his pupil Mazo. After a visit to Naples in 1631, where he worked with his countryman Ribera, and painted a charming portrait of the Infanta Maria, sister of Philip, Velazquez returned early in the year to Madrid.

He then painted the first of many portraits of the young prince, Don Baltasar Carlos, the heir to the throne, dignified and lordly even in his childhood, caracoling in the dress of a field-marshal on his prancing steed. The Wallace collection includes an example which is probably a copy by Mazo; but the finest in the United Kingdom is the well-known picture at Grosvenor House, a masterly example of the second manner of Velazquez. The colour is warm and bright, the workmanship solid and fused like enamel, while light and air pervade every corner. The scene is in the riding-school of the palace, the king and queen looking on from a balcony, while Olivares is in attendance as master of the horse to the prince. Don Baltasar died in 1646 at the age of seventeen, so that judged by his age this picture must have been painted about 1641, two years before the fall of Olivares. This powerful minister was the early and constant patron of the painter. His impassive, saturnine face is familiar to us from the many portraits painted by Velazquez, a face which, like his royal master's, seems never to have known a smile, and in which are written pride and disdain. Two are of surpassing excellence—the full-length formerly in the Holford collection (exhibited at Burlington House in 1887), stately and dignified, in which he wears the green cross of Alcantara and holds a wand, the badge of his office as master of the horse; the other the great equestrian portrait of the Madrid gallery (No. 1069), in which he is flatteringly represented as a field-marshal in all his pomp during an action. It is difficult to overpraise the excellence of this work, either as regards its dramatic power or its masterly execution. In these portraits Velazquez has well repaid the debt of gratitude which he owed to his first patron, whom he stood by in his fall, thus exposing himself to the risk—and it was not a light one—of incurring the anger of the jealous Philip. The king, however, showed no sign of malice towards his favoured painter. Faithful in few things, Philip kept true to Velazquez, whom he visited daily in his studio in the palace, and to whom he stood in many attitudes and costumes, as a huntsman with his dogs, as a warrior in command of his troops, and even on his knees at prayer, wearing ever the same dull uninterested look. His pale face and lack-lustre eye, his fair flowing hair and moustaches curled up to his eyes, and his heavy projecting Austrian under-lip are known in many a portrait and nowhere more supremely than in the wonderful canvas of the London National Gallery (No. 745), where he seems to live and breathe. Few portraits in the whole range of art will compare with this work, in which the consummate handling of Velazquez is seen at its best, for it is in his late and most perfect manner.[1] From one of the equestrian portraits of the king, painted in 1638, the sculptor Montañes modelled a statue which was cast in bronze by the Florentine sculptor Tacca, and which now stands in the Plaza del Oriente at Madrid, "a solid Velazquez," as it has been well named by Ford. This portrait exists no more; but there is no lack of others, for Velazquez was in constant and close attendance on Philip, accompanying him in his journeys to Aragon in 1642 and 1644, and was doubtless present with him when he entered Lerida as a conqueror. It was then that he painted the great equestrian portrait (No. 1066 of the Madrid gallery) in which the king is represented as a great commander leading his troops—a rôle which Philip never played except in a theatrical pageant. All is full of animation except the stolid face of the king. It hangs as a pendant to the great Olivares portrait—fit rivals of the neighbouring Charles V. by Titian, which doubtless fired Velazquez to excel himself, and both remarkable for their silvery tone and their feeling of open air and harmony combined with brilliancy. The light plays on the armour and scarf thrown to the wind, showing how completely Velazquez had mastered the effects he strove to reach in his early days. Of these two great works the Wallace collection includes small but excellent copies.

But, besides the forty portraits of Philip by Velazquez, or attributed to him, we have portraits of other members of the royal family, of Philip's first wife, Isabella of Bourbon, and her children, especially of her eldest son, Don Baltasar Carlos, of whom, besides those already mentioned, there is a beautiful full-length in a private room at Buckingham Palace. Cavaliers, soldiers, churchmen and poets of the court, as for example the Quevedo at Apsley House (shown in Burlington House in 1887), sat to the painter and, even if forgotten by history, will live on his canvas. The Admiral Pulido Pareja from Lord Radnor's collection, now at the National Gallery, is said to have been taken by Philip for the living man; nevertheless, A. de Beruete is emphatic in denying Velazquez's authorship of this picture, which he attributes to Mazo. It has been remarked that the Spaniards have always been chary of committing to canvas the portraits of their beautiful women. Queens and infantas may be painted and exhibited, but ladies rarely. One wonders who the beautiful woman can be that adorns the Wallace collection, the splendid brunette so unlike the usual fair-haired female sitters to Velazquez. She belongs to this period of his work, to the ripeness of his middle period. Instinct with life, her bosom seems to heave and the blood to pulsate through her veins. The touch is firm but free, showing the easy strength of the great master. Rarely has flesh been painted with such a glow; yet with such reserve. This picture is one of the ornaments of the Wallace collection. But, if we have few ladies of the court of Philip, we have in great plenty his buffoons and dwarfs. Even these deformed or half-witted creatures attract our sympathy as we look at their portraits by Velazquez, who, true to his nature, treats them gently and kindly, as in "El Primo" (the Favourite), whose intelligent face and huge folio with ink-bottle and pen by his side show him to be a wiser and better-educated man than many of the gallants of the court. "El Bobo de Coria," "El Niño de Vallecas" and "Pablillos," a buffoon evidently acting a part, all belong to this middle period. From these commissioned portraits of the menials of the court it is pleasant to turn to one of the greatest of historical works, the "Surrender of Breda," often known as "Las Lanzas," from the serried rank of lances breaking the sky, which is believed to have been painted about 1647. It represents the moment when the vanquished Justin of Nassau in front of his Dutch troops is submissively bending as he offers to his conqueror Spinola the keys of the town, which, with courteous grace, the victor refuses to accept, as he lays his hand gently on the shoulder of his defeated foe. Behind Spinola stand the Spanish troops bearing their lances aloft, while beyond is a long stretch of the Low Country, dotted with fortifications and giving the impression of vast space and distance. The picture is full of light and air, and is perhaps the finest example of the silvery bluish style of Velazquez. In conception it is as fine as in execution, and one looks in vain for a trace of "the malicious pencil" which Sir William Stirling-Maxwell discerned in the treatment of Justin and his gallant Dutchmen.

The greatest of the religious paintings by Velazquez belongs also to this middle period, the "Christ on the Cross" (Madrid gallery, No. 1055). Palomino says it was painted in 1638 for

[1] In this and in all his portraits Philip wears the *golilla*, a stiff linen collar projecting at right angles from the neck. It was invented by the king, who was so proud of it that he celebrated it by a festival, followed by a procession to church to thank God for the blessing (Madame D'Aulnoy, *Voyage d'Espagne*). The *golilla* was thus the height of fashion and appears in most of the male portraits of the period. In regard to the wonderful structure of Philip's moustaches, it is said that, to preserve their form, they were encased during the night in perfumed leather covers called *bigoteras*.

the convent of San Placido. It is a work of tremendous power and of great originality, the moment chosen being that immediately after death. The Saviour's head hangs on his breast and a mass of dark tangled hair conceals part of the face. The beautiful form is projected against a black and hopeless sky from which light has been blotted out. The figure stands absolutely alone, without any accessory. The skull and serpent described by Sir William Stirling-Maxwell were added by some pious bungler at a much later date. The picture was lengthened to suit its place in an oratory; but this addition has since been removed. To the same period belongs the great "Boar Hunt" at the National Gallery, a magnificent work in spite of some restorations. The smaller "Boar Hunt" in the Wallace collection is from the brush of Mazo; and the "Conversation, a Group of Thirteen Persons," at the Louvre, a picture which in conception has much in common with these hunting scenes, probably owes its origin to the same artist. A. de Beruete emphatically denies Velazquez's authorship of this much belauded picture, which he describes as a "mediocre imitation, probably by Mazo."

Velazquez's son-in-law Mazo had succeeded him as usher in 1634, and he himself had received steady promotion in the royal household, receiving a pension of 500 ducats in 1640, increased to 700 in 1648, for portraits painted and to be painted, and being appointed inspector of works in the palace in 1647. Philip now entrusted him with the carrying out of a design on which he had long set his heart, the founding of an academy of art in Spain. Rich in pictures, Spain was weak in statuary, and Velazquez was commissioned to proceed to Italy to make purchases. Accompanied by his faithful slave Pareja, whom he taught to be a good painter, he sailed from Malaga in 1649, landing at Genoa, and proceeding thence by Milan to Venice, buying Titians, Tintorettos and Veroneses as he went. A curious conversation which he is said to have had with Salvator Rosa is reported by Boschini,[1] in which the Spaniard with perfect frankness confesses his want of appreciation of Raphael and his admiration of Titian, "first of all Italian men." It seems a possible story, for Velazquez bought according to his likings and painted in the spirit of his own ideals. At Modena he was received with much favour by the duke, and doubtless here he painted the portrait of the duke at the Modena gallery and two splendid portraits which now adorn the Dresden gallery, for these pictures came from the Modena sale of 1746. They presage the advent of the painter's third and latest manner, a noble example of which is the great portrait of Innocent X. in the Doria palace at Rome, to which city Velazquez now proceeded. There he was received with marked favour by the pope, who presented him with a medal and gold chain. Of this portrait, thought by Sir Joshua Reynolds to be the finest picture in Rome, Palomino says that Velazquez took a copy to Spain. There exist several in different galleries, some of them possibly studies for the original or replicas painted for Philip. One of the most remarkable is that in Apsley House, exhibited in Burlington House in 1887. The modelling of the stern impassive face comes near to perfection, so delicate are the gradations in the full light; all sharpness of outline has disappeared; and the features seem moulded by the broad and masterly brushwork. When closely examined, the work seems coarse, yet at the proper distance it gives the very essence of living flesh. The handling is rapid but unerring. Velazquez had now reached the *manera abreviada*, as the Spaniards call this bolder style. This is but another way of saying that his early and laborious studies and his close observation of nature had given to him in due time, as to all great painters, the power of representing what he saw by simpler means and with more absolute truth. At Rome he painted also a portrait of his servant Pareja, probably the picture of Lord Radnor's collection, which procured his election into the academy of St Luke. Philip was now wearying for his return; accordingly, after a visit to Naples, where he saw his old friend Ribera, he returned to Spain by Barcelona in 1651, taking with him many pictures and 300 pieces of statuary, which he afterwards arranged and catalogued for the king. Undraped sculpture was, however, abhorrent to the Spanish Church, and after Philip's death these works gradually disappeared.

Isabella of Bourbon had died in 1644, and the king had married Mariana of Austria, whom Velazquez now painted in many attitudes. He was specially chosen by the king to fill the high office of "aposentador major," which imposed on him the duty of looking after the quarters occupied by the court whether at home or in their journeys—a responsible function, which was no sinecure and interfered with the exercise of his art. Yet far from indicating any decline, his works of this period are amongst the highest examples of his style. The dwarf "Don Antonio el Inglés" (the Englishman) with his dog, "Aesop," "Menippus" and "the Sculptor Montañes," all in the Madrid gallery, show his surest and freest manner. To these may be added the charming portraits of the royal children in the Louvre and Vienna, among the choicest of his works. It is one of these infantas, Margarita Maria, the eldest daughter of the new queen, that is the subject of the well-known picture "Las Meniñas" (the Maids of Honour), 1062, in the Madrid gallery, painted in 1656, where the little lady holds court, surrounded by her ladies-in-waiting, her dwarfs and her mastiff, while Velazquez is seen standing at his easel. This is the finest portrait we have of the great painter. It is a face of much dignity, power and sweetness—like his life, equable and serene, unruffled by care. "Las Meniñas" was the picture of which Luca Giordano said that it was the "theology of painting," another way of expressing the opinion of Sir Thomas Lawrence, that this work is the philosophy of art, so true is it in rendering the desired effect. The result is there, one knows not by what means, as if by a first intention without labour, absolutely right. The story is told that the king painted the red cross of Santiago on the breast of the painter, as it appears to-day on the canvas. Velazquez did not, however, receive the honour till 1659, three years after the execution of this work. Even the powerful king of Spain could not make his favourite a belted knight without a commission to inquire into the purity of his lineage on both sides of the house. The records of this commission have been found among the archives of the order of Santiago by M. Villaamil. Fortunately the pedigree could bear scrutiny, as for generations the family was found free from all taint of heresy, from all trace of Jewish or Moorish blood and from contamination by trade or commerce. The difficulty connected with the fact that he was a painter was got over by his being painter to the king and by the declaration that he did not sell his pictures. But for this royal appointment, which enabled him to escape the censorship of the Inquisition, we should never have had his splendid "Venus and Cupid," formerly belonging to Mr Morritt of Rokeby Hall and bought by the National Art Collections Fund for £45,000 for the National Gallery in 1905. It is painted in his latest manner and is worthy of comparison with Titian.[2] There were in truth but two patrons of art in Spain—the church and the art-loving king and court. Murillo was the artist favoured by the church, while Velazquez was patronized by the crown. One difference, however, deserves to be noted. Murillo, who toiled for a rich and powerful church, left scarcely sufficient means to pay for his burial, while Velazquez lived and died in the enjoyment of good salaries and pensions. Yet on occasions Philip gave commissions for religious pictures to Velazquez—among others, and belonging to this later period, the "Coronation of the Virgin" (Madrid, 1056), splendid in colour—a harmony of red, blue and grey—but deficient in religious feeling and dignity. It was painted for the oratory of the queen, doubtless Mariana, in the palace at Madrid. Another royal commission for the hermitage of Buen Retiro was the "St Anthony the Abbot and St Paul the Hermit," painted in 1659, the landscape

[1] See Stirling-Maxwell's *Velazquez and his Works*, p. 161.

[2] Some uncertainties in the proprietorial history of this picture have led to considerable discussion concerning its authenticity. But the suggestion that Mazo's signature could be detected on it was repudiated by an expert committee in 1910 who carefully examined the painting.

of which excited the warm admiration of Sir David Wilkie (No. 1057 in the Prado). The last of his works which we shall name is "Las Hilanderas" or the Spinners (Madrid, 1061), painted about 1656, representing the interior of the royal tapestry works. The subject is nothing, the treatment everything. It is full of light, air and movement, splendid in colour and marvellous in handling. This picture, Raphael Mengs said, seemed to have been painted not by the hand but by the pure force of will. We see in it the full ripeness of the power of Velazquez, a concentration of all the art-knowledge he had gathered during his long artistic career of more than forty years. In no picture is he greater as a colourist. The scheme is simple—a harmony of red, bluish-green, grey and black, which are varied and blended with consummate skill.

In 1660 a treaty of peace between France and Spain was to be consummated by the marriage of the infanta Maria Theresa with Louis XIV., and the ceremony was to take place in the Island of Pheasants, a small swampy island in the Bidassoa. Velazquez was charged with the decoration of the Spanish pavilion and with the whole scenic display. In the midst of the grandees of the first two courts in Christendom Velazquez attracted much attention by the nobility of his bearing and the splendour of his costume. On the 26th of June he returned to Madrid, and on the 31st of July he was stricken with fever. Feeling his end approaching, he signed his will, appointing as his sole executors his wife and his firm friend Fuensalida, keeper of the royal records. He died on the 6th of August 1660, passing away in the full possession of his great powers, and leaving no work behind him to show a trace of decay. He was buried in the Fuensalida vault of the church of San Juan, and within eight days his wife Juana was laid beside him. Unfortunately this church was destroyed by the French in 1811, so that his place of interment is now unknown. There was much difficulty in adjusting the tangled accounts outstanding between Velazquez and the treasury, and it was not till 1666, after the death of Philip, that they were finally settled.

Velazquez can hardly be said to have formed a school of painting. Apart from the circumstance that his occupations at court would have prevented this, his genius was too personal for transmission by teaching. Yet his influence on those immediately connected with him was considerable. In 1642 he befriended young Murillo on his arrival in Madrid, received him into his house, and directed his studies for three years. His son-in-law Mazo painted in his manner, and doubtless many pictures by Mazo are attributed to the master. Carreño, though never a pupil, was a favourite and had the good sense to appreciate him and imitate him. His faithful slave Pareja studied his methods and produced work which by the favour of Velazquez procured his manumission from Philip. But the appreciation of the fine talent of Velazquez passed away quickly in Spain, as that country began to fall to pieces.

In addition to the standard works by Palomino (1724), Cean Bermudez (1800) and Pacheco (1649), see the biographical notice by Don Pedro de Madrazo in his *Catalogo del Museo del Prado* (1872); *Velazquez and his Works* (1855) and *Annals of Artists of Spain* (1848), by W. Stirling (afterwards Sir W. Stirling-Maxwell); Ford's *Handbook to Spain* (1855) and his article in the *English Cyclopaedia*; *Velazquez and Murillo*, by Charles B. Curtis (1883); the works of W. Burger (T. Thoré); *Gesch. d. Malerei*, by Woltmann and Woermann; Sir Edmund Head's *Handbook of Spanish Painting* (1848); *Works of Velazquez* (prints), by G. W. Reid (1872); *Gaz. d. Beaux Arts*, art. "Velazquez," by Paul Lefort (second period, 1879–82); Carl Justi, *Diego Velazquez u. sein Jahrhundert* (2 vols., Bonn, 1888); *The Life of Velazquez*, by Sir Walter Armstrong (London, 1896); *Velazquez*, by R. A. M. Stevenson (London, 1899); *Velazquez outside the Prado Museum*, by Don Manuel Mesonero Romanos (Madrid, 1899); *The Life and Works of Don Diego Velazquez*, by Don Jacinto Octavio Picon (Madrid, 1899); *Days with Velazquez*, by C. Lewis Hind (London, 1906); and, finally, Don A. de Beruete's standard work on the subject, *Velazquez* (London, 1906), which contains reproductions of all the master's paintings of which the author admits the authenticity. (J. F. W.; P. G. K.)

VELEIA, an ancient town of Aemilia, Italy, situated about 20 m. S. of Placentia. It is mentioned by Pliny among the towns of the eighth region, though the Veleiates were Ligurians by race. Its inhabitants were in the census of Vespasian found to be remarkable for their longevity. Nothing further was known of it until 1747, when some ploughmen found the famous *Tabula alimentaria*, now in the museum at Parma. This, the largest inscribed bronze tablet of antiquity (4 ft. 6 in. by 9 ft. 6 in.) contains the list of estates in the territories of Veleia, Libarna, Placentia, Parma and Luca, in which Trajan had assigned before 102 B.C. 72,000 sesterces (£720) and then 1,044,000 sesterces (£10,440), on a mortgage bond to forty-six estates, the total value of which was reckoned at over 13,000,000 sesterces (£130,000), the interest on which at 5% was to serve for the support of 266 boys and 36 girls, the former receiving 16, the latter 12 sesterces a month. See *Ligures Baebiani* for a similar inscription. Excavations were begun on the site in 1760, and were at first successful; the forum and basilica, the thermae and the amphitheatre, private houses, &c., with many statues (twelve of marble from the basilica, and a fine bronze head of Hadrian) and inscriptions were discovered. Pre-Roman cremation tombs have also been found, with objects of bronze and iron of no great value. But later excavations which were carried on at intervals up to 1876 have given less fruitful results. The oldest dated monument is a bronze tablet with a portion of the text of the *Lex Rubria* of 49 B.C. which dealt with the administration of justice in Cisalpine Gaul in connexion with the extension to it of the privileges of the Roman franchise, the latest an inscription of A.D. 276. How and when it was abandoned is uncertain: the previously prevalent view that it was destroyed by a landslip was proved to be mistaken by the excavations of 1876. Most of the objects found are in the museum at Parma.

See G. Antolini, *Le Rovine di Veleia* (Milan, 1831); G. Mariotti in *Notizie degli Scavi* (1877), 157; E. Bormann in *Corpus Inscript. Latin* (Berlin, 1888), xi. 204 sqq. (T. As.)

VÉLEZ-MÁLAGA, a town of southern Spain, in the province of Málaga, finely situated in a fertile valley at the southern base of the lofty Sierra de Alhama, and on the left bank of the small river Vélez, 1 m. from its mouth and 27 m. by road E.N.E. of Málaga. Pop. (1900) 23,586. Vélez-Málaga formerly was a place of considerable commercial importance, but its prosperity has much declined; there is no railway, and the town suffered severely in the earthquakes of 1884 and the floods of 1907. The vegetation of the neighbourhood is most luxuriant, including the aloe, palm, sugar-cane, prickly pear, orange, vine, olive and sweet potato. Vélez-Málaga was held by the Moors from 711 to 1487, when it was captured by Ferdinand of Castile. Under Moorish rule the citadel was built and the town became an important trading station and fortress. Its harbour, the Vélez estuary, affords good anchorage and is well sheltered.

VELIA (Gr. Ὑέλη, later Ἐλέα), an ancient town of Lucania, Italy, on the hill now crowned by the medieval castle of Castellammare della Bruca, 440 ft. above sea-level, on the S.W. coast, 1¾ m. N.W. of the modern railway station of Ascéa, 25 m. S.E. of Paestum. Remains of the city walls, with traces of one gate and several towers, of a total length of over 3 m., still exist, and belong to three different periods, in all of which the crystalline limestone of the locality is used. Bricks were also employed in later times; their form is peculiar to this place, each having two rectangular channels on one side, and being about 15 in. square, with a thickness of nearly 4 in. They all bear Greek brick-stamps. There are some remains of cisterns on the site, and various other traces of buildings. The town was mainly celebrated for the philosophers who bore its name (see ELEATIC SCHOOL). About 530 B.C. the Phocaeans, driven from Corsica, seized it from the Oenotrians. Its coins were widely diffused in S. Italy, and it kept its independence even in Roman times, and only became a *municipium* after the Social War.

See W. Schlenning in *Jahrbuch des K. Deutschen Arch. Instituts* (1889), iv. 169 sqq. (T. As.)

VELIUS LONGUS (2nd cent. A.D.), Latin grammarian during the reign of Trajan (or Hadrian), author of an extant treatise on Orthography (H. Keil, *Grammatici Latini*, vii.). He is mentioned by Macrobius (*Saturnalia*, iii. 6, 6) and Servius (on *Aen.* x. 245) as a commentator on Virgil.

See M. Schanz, *Geschichte der römischen Litteratur*, iv. 1 (1904); Teuffel, *Hist. of Roman Literature* (Eng. trans., 1900), 343, 2.

VELLEIUS PATERCULUS, MARCUS (*c.* 19 B.C.–*c.* A.D. 31), Roman historian. Although his praenomen is given as Marcus by Priscian, some modern scholars identify him with Gaius Velleius Paterculus, whose name occurs in an inscription on a north African milestone (*C.I.L.* viii. 10, 311). He belonged to a distinguished Campanian family, and early entered the army. He served as military tribune in Thrace, Macedonia, Greece and the East, and in A.D. 2 was present at the interview on the Euphrates between Gaius Caesar, grandson of Augustus, and the Parthian king. Afterwards, as praefect of cavalry and legatus, he served for eight years (from A.D. 4) in Germany and Pannonia under Tiberius. For his services he was rewarded with the quaestorship in 7, and, together with his brother, with the praetorship in 15. He was still alive in 30, for history contains many references to the consulship of M. Vinicius in that year. It has been conjectured that he was put to death in 31 as a friend of Sejanus, whose praises he celebrates in a most fulsome manner.

He wrote a compendium of Roman history in two books dedicated to M. Vinicius, from the dispersion of the Greeks after the siege of Troy down to the death of Livia (A.D. 29). The first book brings the history down to the destruction of Carthage, 146 B.C.; portions of it are wanting, including the beginning. The later history, especially the period from the death of Caesar, 44 B.C., to the death of Augustus, A.D. 14, is treated in much greater detail. Brief notices are given of Greek and Roman literature, but it is strange that no mention is made of Plautus, Horace and Propertius. The author is a vain and shallow courtier, and destitute of real historical insight, although generally trustworthy in his statements of individual facts. He may be regarded as a courtly annalist rather than an historian. His knowledge is superficial, his blunders numerous, his chronology inconsistent. He labours at portrait-painting, but his portraits are daubs. On Caesar, Augustus and above all on his patron Tiberius, he lavishes praise or flattery. The repetitions, redundancies, and slovenliness of expression which disfigure the work may be partly due to the haste with which (as the author frequently reminds us) it was written. Some blemishes of style, particularly the clumsy and involved structure of his sentences, may perhaps be ascribed to insufficient literary training. The inflated rhetoric, the straining after effect by means of hyperbole, antithesis and epigram, mark the degenerate taste of the Silver Age, of which Paterculus is the earliest example. He purposed to write a fuller history of the later period, which should include the civil war between Caesar and Pompey and the wars of Tiberius; but there is no evidence that he carried out this intention. His chief authorities were Cato's *Origines*, the *Annales* of Q. Hortensius, Pompeius Trogus, Cornelius Nepos and Livy.

Velleius Paterculus was little known in antiquity. He seems to have been read by Lucan and imitated by Sulpicius Severus, but he is mentioned only by the scholiast on Lucan, and once by Priscian. The text of the work, preserved in a single badly written and mutilated MS. (discovered by Beatus Rhenanus in 1515 in the abbey of Murbach in Alsace and now lost), is very corrupt. Editio princeps, 1520; early editions by the great scholars Justus Lipsius, J. Gruter, N. Heinsius, P. Burmann; modern editions, Ruhnken and Frotscher (1830–39), J. C. Orelli (1835), F. Kritz (1840, ed. min. 1848), F. Haase (1858), C. Halm (1876), R. Ellis (1898) (reviewed by W. Warde Fowler in *Classical Review*, May 1899); on the sources see F. Burmeister, "De Fontibus Vellei Paterculi," in *Berliner Studien für classische Philologie* (1894), xv. English translation by J. S. Watson in Bohn's Classical Library.

VELLETRI (anc. *Velitrae*), a town and episcopal see of the province of Rome, Italy, at the south-east foot of the outer ring wall of the Alban crater, 26 m. S.E. of Rome by rail, 1155 ft. above sea-level. Pop. (1901) 14,243 (town), 18,734 (commune). It is the seat of the bishop of Ostia, and has a statue of Pope Clement VIII. Good wine is made in the fertile vineyards of the district, and there is a government experimental station for viticulture. Velletri is the junction of the Terracina line and a branch to Segni on the main line to Naples. Velletri has a fine view of the Volscian mountains and over the Pomptine Marshes to the Circeian promontory. The town contains a few objects of interest; at the highest point is the prominent municipal palace, containing a few ancient inscriptions, among them one relating to a restoration of the amphitheatre under Valentinian and Valens. The internal façade of the Palazzo Ginetti is finely decorated with stucco, and has a curious detached baroque staircase by Martino Lunghi the younger, which Burckhardt calls unique if only for the view to which its arched colonnades serve as a frame. The lofty campanile of S. Maria in Trivio, erected in 1353 in gratitude for the liberation of the city from a plague which devastated it in 1348, is in the style of contemporary brick campanili in Rome, but built mainly of black selce, with white marble columns at the windows. The cathedral (the see of the titular bishop of Ostia) was reconstructed in 1660, but contains traces of the older structure. Of the ancient town nothing practically remains above ground; scanty traces of the city walls have been excavated (and covered again) near the railway station, and the present walls are entirely medieval.

The ancient city of Velitrae was Volscian in Republican times, and it is the only Volscian town of which an inscription in that language is preserved (4th century B.C.). It mentions the two principal magistrates as *medix*. It was, however, a member of the Latin League in 499 B.C., so that in origin it may have been Latin and have fallen into Volscian hands later. It was important as commanding the approach to the valley between the Alban and Volscian mountains. In 494 it was taken from the Volscians and became a Roman colony. This was strengthened in 404, but in 393 Velitrae regained its freedom and was Rome's strongest opponent; it was only reduced in 338, when the freedom of Latium finally perished. Its resistance was punished by the destruction of its walls and the banishment of its town councillors to Etruria, while their lands were handed over to Roman colonists. We hear little or nothing of it subsequently except as the home of the *gens Octavia*, to which the Emperor Augustus belonged. The neighbourhood contains some remains of villas, but not proportionately very many; there are more on the side towards Lanuvium (W.). The Via Appia passed considerably below the town (some 5 m. away), which was reached by a branch road from it, diverging at the post station of Sublanuvio. During the whole of the middle ages it was subject to the papacy.

(T. As.)

VELLORE, a town of British India, in the North Arcot district of Madras, on the river Palar and the South Indian railway, 87 m. W. of Madras city. Pop. (1901) 43,537. It has a strongly built fortress, which was famous in the wars of the Carnatic. It dates traditionally from the 13th century, but more probably only from the 17th. It is a fine example of Indian military architecture, and contains a temple adorned with admirable sculptures. In 1780 it withstood a siege for two years by Hyder Ali. After the fall of Seringapatam (1799) Vellore was selected as the residence of the sons of Tippoo Sahib, and to their intrigues has been attributed the mutiny of the sepoys here in 1806. An American mission manages a high school, raised to the rank of a college in 1898; and the police training school for the presidency is also situated here. Vellore has a large grain trade, and flowers are cultivated in the vicinity.

VELVET, a silken textile fabric having a short dense piled surface. In all probability the art of velvet-weaving originated in the Far East; and it is not till about the beginning of the 14th century that we find any mention of the textile. The peculiar properties of velvet, the splendid yet softened depth of dye-colour it exhibited, at once marked it out as a fit material for ecclesiastical vestments, royal and state robes, and sumptuous hangings; and the most magnificent textures of medieval times were Italian velvets. These were in many ways most effectively treated for ornamentation, such as by varying the colour of the pile, by producing pile of different lengths (pile upon pile, or double pile), and by brocading with plain silk, with uncut pile or with a ground of gold tissue, &c. The earliest sources of European artistic velvets were Lucca, Genoa, Florence and Venice, and Genoa continues to send out rich velvet textures. Somewhat later the art was taken up by Flemish weavers, and in the 16th century Bruges attained a reputation for velvets not inferior to that of the great Italian cities.

VELVETEEN, a cotton cloth made in imitation of velvet. The term is sometimes applied to a mixture of silk and cotton. Some velveteens are a kind of fustian, having a rib of velvet pile alternating with a plain depression. The velveteen trade varies a good deal with the fashions that control the production of velvet. Velveteens are commonly woven in sheeting looms, and manufacturers are able to alternate the two kinds of goods according to the demand.

VENAFRUM, an ancient town of Campania, Italy, close to the boundaries of both Latium adjectum and Samnium. Its site is occupied by the modern Venafro, a village with 4716 inhabitants (1901), on the railway from Isernia to Caianello, 15 m. S.W. of the former, 658 ft. above sea-level. Ancient authors tell us but little about it, except that it was one of those towns governed by a prefect sent yearly from Rome, and that in the Social War it was taken by the allies by treachery. Augustus founded a colony there and provided for the construction of an aqueduct (cf. the long decree relating to it in *Corp. Inscr. Lat.* x. No. 4842). It seems to have been a place of some importance. Its olive oil was the best in Italy, and Cato mentions its brickworks and iron manufactures. The original line of the Via Latina probably ran through Venafrum, making a détour, which the later road seems to have avoided (cf. LATINA, VIA). Rufrae was probably dependent on it. Roads also ran from Venafrum to Aesernia and to Telesia by way of Allifae. Of ancient remains hardly anything is left—some traces of an amphitheatre and fragments of polygonal walls only. (T. As.)

VENDACE, the name of a British freshwater fish of the genus *Coregonus*, of which two other species are indigenous in the fresh waters of the British Islands, the gwyniad and the pollan. The vendace (*C. vandesius*) is restricted to some lochs in Dumfriesshire, Scotland; it is, however, very similar to a species (*C. albula*) which inhabits some of the large and deep lakes of northern Europe. From its general resemblance to a dace the French name of the latter, *vandoise*, was transferred to it at the period when French was the language of the court and aristocracy of Scotland. So great is the local celebrity of the fish that a story has been invented ascribing to Mary Queen of Scots the merit of having introduced it into the Lochmaben lochs. It is considered a great delicacy, and on favourable days when the shoals rise to the surface, near the edges of the loch, great numbers may be taken. It spawns in November. In length it scarcely exceeds 8 in.

VENDÉE, a maritime department of western France, formed in 1790 out of Bas-Poitou, and taking its name from an unimportant tributary of the Sèvre Niortaise. It is bounded by Loire-Inférieure and Maine-et-Loire on the N., by Deux-Sèvres on the E., by Charente-Inférieure on the S. and by the Atlantic Ocean on the W. for 93 m. Pop. (1906) 442,777. Area, 2708 sq. m. The islands of Yeu (area, 8½ sq. m.) and Noirmoutier (*q.v.*) are included. The Sèvre Nantaise on the N.E. and the Sèvre Niortaise on the S., besides other streams of minor importance, form natural boundaries. The department falls into three divisions—woodland (*Bocage*), plain (*Côte*) and marsh (*Marais*).

The highest point (748 ft.) is situated in the woodland, which occupies the greater part of Vendée, on the water-parting between the Loire and the rivers of the coast. This region, which, geologically, is composed of granite, gneiss, mica-schist, schist and lias, abounds in springs, and is fresh and verdant; the landscape is characterized by open fields surrounded by trees, which supplied ambushes and retreats to the Vendéans in the civil war at the end of the 18th century. The marshes, raised above the sea-level within historic times (four centuries ago), consist of two portions, the Breton marsh in the north and the Poitevin marsh in the south; the latter extends into the departments of Charente-Inférieure and Deux-Sèvres. The region includes productive salt marshes and fertile cultivated areas artificially drained. Its area is constantly being increased by the alluvium of the rivers and the secular elevation of the coast. The celebrated beds of sea-shells near St Michel en l'Herm—2300 ft. long, 985 ft. broad and from 30 to 50 ft. deep—show to what extent the coast has risen. The plain of Vendée lying between the Bocage and the Poitevin marsh is bare and treeless, but fertile, though poor in springs; geologically it is composed of lias and oolite. The department is drained by the Sèvre Nantaise (tributary of the Loire) and the Boulogne (a feeder of Lake Grandlieu in Loire-Inférieure), both draining into the basin of the Loire; and by the Vie, the Lay (with the Yon), and the Sèvre Niortaise (with the Autise and the Vendée), which flow into the Atlantic. The climate is that of the Girondine region, mild and damp, the temperature rarely rising above 77° or falling below 18° F.; 120 to 150 days of rain give an average annual rainfall of 25 in. The woodland is colder than the plain, and the marsh is damp and unhealthy.

The department is agriculturally prosperous. Wheat is the most important crop, oats, potatoes, clover, lucerne and mangold-wurzels ranking next. Beans, flax and colza may also be mentioned. Wine is grown in the south of the department. The rearing of live stock flourishes in the Bocage and the marsh, the pastures of the latter nourishing fine oxen and horses, and sheep famous for the excellence of their mutton. Cider-apples, pears, peaches, plums, cherries and walnuts are among the fruits grown. Coal is mined in the south-east of the department (basin of Vouvant) and antimony is found; limestone is quarried. The spinning and weaving of wool, cotton and flax is carried on, and there are potteries, paper-mills, tan-yards, dye-works, manufactories of hats, boots and shoes, glass and lampblack, flour-mills, distilleries, oil-works, tile-works and shipbuilding yards. Sardines and tinned foods are prepared. The sardine fishery is active on the coast and there are extensive oyster-beds near Sables-d'Olonne. Corn, cattle, mules, fish, salt, wine, honey, wood, glass and manure are exported; wine, wood, building material, coal, phosphates and petroleum are among the imports. Sables-d'Olonne is the principal fishing and commercial port.

Vendée is served by the Ouest-État railway and has 81 m. of navigable rivers and canals. The department forms the diocese of Luçon, has its court of appeal and educational centre at Poitiers, and is included in the district of the XI. Army Corps (headquarters at Nantes). There are three arrondissements (La Roche-sur-Yon, Fontenay-le-Comte and Sables-d'Olonne), 30 cantons, and 304 communes. The principal towns are La Roche-sur-Yon, Les Sables-d'Olonne, Fontenay-le-Comte and Luçon, which are treated under separate headings. Other places of interest are Foussais, Nieul-sur-l'Autise and Vouvant, with Romanesque churches; Pouzauges, which has a stronghold of the 13th century; Maillezais, with the ruins of its old cathedral; Talmont and Tiffauges, both possessing ruined castles; and Le Bernard with noteworthy megalithic remains.

VENDÉE, WARS OF THE, a counter-revolutionary insurrection which took place during the French Revolution (*q.v.*), not only in Vendée proper but also in Lower Poitou, Anjou, Lower Maine and Brittany. The district was mainly inhabited by peasants; it contained few important towns, and the *bourgeois* were but a feeble minority. The ideas of the Revolution were slow in penetrating to this ignorant peasant population, which had always been less civilized than the majority of Frenchmen, and in 1789 the events which roused enthusiasm throughout the rest of France left the Vendéans indifferent. Presently, too, signs of discontent appeared. The priests who had refused to submit to the Civil Constitution of the Clergy perambulated these retired districts, and stigmatized the revolutionists as heretics. In 1791 two "representatives on mission" informed the Convention of the disquieting condition of Vendée, and this news was quickly followed by the exposure of a royalist plot organized by the marquis de la Rouërie.

The signal for a widespread rising was the introduction of conscription acts for the recruiting of the depleted armies on the eastern frontiers. In February 1793 the Convention decreed a levy on the whole of France, and on the eve of the ballot the Vendée, rather than comply with this requisition, broke out in insurrection. The Vendéan peasant refused to join the republican army, not for want of fighting qualities or ardour, but because the army of the old régime was recruited from bad characters and broken men, and the peasant, ignorant of the great change that had followed the Revolution, thought that the barrack-room was no place for a good Christian. In March 1793 the officer commanding at Cholet was killed, and republicans were massacred at Machecoul and St Florent. Giving rein to their ancient antipathy, the revolted peasantry attacked the towns, which were liberal in ideas and republican in sympathies. The leaders of these first risings were men of humble birth, such as J. Cathelineau, a pedlar, J. N. Stofflet, a gamekeeper, and the barber Gaston. Cholet, Bressuire, Fontenay-le-Comte and Samur were surprised. The influence of the priests kept up the fanaticism of the peasants, and a great manifestation of religious feeling took place on Easter eve, but the republican soldiers taken prisoners were often maltreated and even tortured.

These first successes of the Vendéans coincided with grave republican reverses on the frontier—war with England, Holland and Spain, the defeat of Neerwinden and the defection of Dumouriez. The *émigrés* then began to throw in their lot with the Vendéans. Royalist nobles like the marquis de Bonchamp, F. A. Charette de la Contrie, Gigot d'Elbée, Henri de la Rochejaquelein and the marquis de Lescure placed themselves at the head of the peasants. Although several of these leaders were Voltairians, they held up Louis XVI., who had been executed in January 1793, as a martyr to Catholicism, and the Vendéans, who had hitherto styled themselves the Christian Army, now adopted the name of the Catholic and Royal Army.

The Convention took measures against the *émigrés* and the refractory priests. By a decree of the 19th of March 1793 every person accused of taking part in the counter-revolutionary revolts, or of wearing the white cockade (the royalist emblem), was declared an outlaw. The prisoners were to be tried by military commissions, and the sole penalty was death with confiscation of property. The Convention also sent representatives on mission into Vendée to effect the purging of the municipalities, the reorganization of the national guards in the republican towns, and the active prosecution of the revolutionary propaganda. These measures proving insufficient, a decree was promulgated on the 30th of April 1793 for the despatch of regular troops; but, in spite of their failure to capture Nantes (where Cathelineau was mortally wounded), the successes of the Vendéans continued. On the 31st of July, therefore, at Barère's suggestion, it was decreed that the woods of the Vendée should be burnt, the harvest carried off to safe places in rear of the army, the cattle seized, the women and children concentrated in camps in the interior, and that every male from the age of sixteen in the neighbouring regions should be called upon to take arms. Further, on the 1st of August, the troops that had formed the garrison of Mainz, which were unavailable against foreign enemies by the terms of their capitulation to the Austrians, were ordered to Vendée. The programme was carried out by the so-called "infernal columns."

At the end of August 1793, the republicans had three armies in the Vendée—the army of Rochelle, the army of Brest and the *Mayençais*; but their generals were either ciphers, like C. P. H. Ronsin, or divided among themselves, like J. A. Rossignol and J. B. C. Canclaux. They were uncertain whether to cut off the Vendéans from the sea or to drive them westwards; and moreover, their men were undisciplined. Although the peasants had to leave their chiefs and work on the land, the Vendéans still remained formidable opponents. They were equipped partly with arms supplied by England, and partly with fowling-pieces, which at that period were superior to the small-arms used by the regular troops, and their intimate knowledge of the country gave them an immense advantage. They gathered and burst like a storm on their enemies, and, if repulsed, dispersed at the famous order, "Egaillez-vous les gars," to unite again some days later.

The dissensions of the republican leaders and the demoralizing tactics of the Vendéans resulted in republican defeats at Chantonnay, Torfou, Coron, St Lambert, Montaigu and St Fulgent. The Convention resolved to bring the war to an end before October, and placed the troops under the undivided command, first of Jean Léchelle and then of Louis Turreau, who had as subordinates such men as Marceau, Kléber and Westermann. On the 7th of October the various divisions concentrated at Bressuire, took Châtillon after two bloody engagements, and defeated the Vendéans at Cholet, Beaupréau and La Tremblaye. After this repulse, the royalists, under Stofflet and La Rochejaquelein, attempted to rouse the Cotentin and crossed the Loire. Beaten back at Granville, they tried to re-enter the Vendée, but were repulsed at Angers. They re-formed at Le Mans, where they were defeated by Westermann, and the same officer definitively annihilated the main body of the insurgents at Savenay (December 1793).

Regular warfare was now at an end, although Turreau and his "infernal columns" still continued to scour the disaffected districts. After the 9th Thermidor attempts were made to pacify the country. The Convention issued conciliatory proclamations allowing the Vendéans liberty of worship and guaranteeing their property. General Hoche applied these measures with great success. He restored their cattle to the peasants who submitted, "let the priests have a few crowns," and on the 20th of July 1795 annihilated an *émigré* expedition which had been equipped in England and had seized Fort Penthièvre and Quiberon. Treaties were concluded at La Jaunaie (February 15, 1795) and at La Mabillaie, and were fairly well observed by the Vendéans; and nothing remained but to cope with the feeble and scattered remnant of the Vendéans still under arms, and with the Chouans (*q.v.*). On the 30th of July 1796 the state of siege was raised in the western departments.

During the Hundred Days there was a revival of the Vendéan war, the suppression of which occupied a large corps of Napoleon's army, and in a measure weakened him in the northern theatre of war (see WATERLOO CAMPAIGN).

In 1832 again an abortive insurrection broke out in support of the Bourbons, at the instigation of the duchess of Berry; the Vendéan hero on this occasion was the baron de Charette.

There are numerous articles on the Vendéan insurrection of 1793 in the *Revue du Bas-Poitou*, *Revue historique de l'Anjou*, *Revue de Bretagne, de Vendée et d'Anjou*, *Revue historique de l'Ouest*, *Revue historique et archéologique du Maine*, and *La Vendée historique*. See also R. Bittard des Portes, "Bibliographie historique et critique des guerres de Vendée et de la Chouannerie" in the *Revue du Bas-Poitou* (1903 seq.); C. L. Chassin, *Études sur la Vendée et la Chouannerie* (*La Préparation de la guerre—La Vendée patriote—Les Pacifications de l'Ouest*), Paris, 1892 seq., 11 vols. (the best general work on the subject); C. Port, *Les Origines de la Vendée* (Paris, 1888); C. Mautouchet, *Le Conventionnel Philippeaux* (Paris, 1901). On 1815 a modern work is *Les Cent Jours en Vendée; le général Lamarque*, by B. Lasserre (Paris, 1907); on 1832 see *La Vendée*, by Vicomte A. de Courson (1909). (R. A.*)

VENDÉMIAIRE (from Lat. *vindemia*, vintage), the name given during the French Revolution to the first month of the year in the Republican Calendar. Vendémiaire began on the 22nd, 23rd or 24th of September, and ended on the 22nd, 23rd or 24th of October according to the year, and was the season of the vintage in the wine districts of northern France. In accordance with the suggestion of Fabre d'Eglantine, each of the days of the republican year was consecrated to some useful object. For instance, 1 Vendémiaire was the festival of the grape, 10 Vendémiaire of the vat, 13 Vendémiaire of the pumpkin, 15 Vendémiaire of the ass, 20 Vendémiaire of the wine-press, and 30 Vendémiaire of the cask. The most important event in this month was the quelling of the royalist rising on 13 Vendémiaire year IV. (4th of October 1795), in which General Bonaparte (afterwards the emperor Napoleon) distinguished himself by his energy and skill in using artillery.

See Baron R. de Larcy, *Le 13 Vendémiaire* (Paris, 1872).

VENDETTA (Ital. from Lat. *vindicta*, revenge, *vindicare*, to defend oneself), the term applied to the custom of the family feud, by which the nearest kinsman of a murdered man was obliged to take up the quarrel and avenge his death. From being an obligation upon the nearest, it grew to be an obligation on all the relatives, involving families in bitter private wars among themselves. It is a development of that stage in civilization common to all primitive communities, when the injury done was held to be more than personal, a wrong done to the whole *gens*.

The term originated in Corsica, where the vendetta has long played an important part in the social life. If the murderer could not be found, his family were liable to fall victims to the vendetta. The feud was sometimes complicated by the *vendetta transversale*, when each of two branches of a family had a murder to revenge on the other. In Corsica it was regarded as the most sacred family duty. Mediators (*parolanti*) sometimes intervened successfully to end the feuds, and extort an oath to forgo vengeance. The custom still survives in Corsica in its complete form, and partially in Sardinia, Sicily, Montenegro, Afghanistan, among the Mainotes of Greece, the Albanians, Druses and Bedouins.

VENDÔME, LOUIS JOSEPH, Duc de (1654–1712), marshal of France, was the son of Louis, 2nd duke of Vendôme, and the great-grandson of Henry IV. and Gabrielle d'Estrées. Entering the army at the age of eighteen he soon distinguished himself by his vigour and personal courage in the Dutch wars, and by 1688 he had risen to the rank of lieutenant-general. In the war of the Grand Alliance he rendered conspicuous service under Luxemburg at Steinkirk and under Catinat at Marsaglia, and in 1695 he was placed in command of the army operating in Catalonia where he took Barcelona. Soon afterwards he received the marshalate. In 1702, after the first unsuccessful campaign of Catinat and Villeroi, he was placed in command of the Franco-Spanish army in Italy (see Spanish Succession War). During three campaigns in that country he proved himself a worthy antagonist to Prince Eugene, whom at last he defeated at Cassano by his magnificent courage and command over his troops, converting the defeat that his indolent brother, the Grand Prior, had incurred into a glorious success. Next year, after holding his own as before, he was sent to Flanders to repair the disaster of Ramillies with the result that his successors Marsin and Philip of Orleans were totally defeated, while in the new sphere Vendôme was merely the mentor of the pious and unenterprising duke of Burgundy, and was unable to prevent the defeat of Oudenarde. He therefore retired in disgust to his estates, but it was not long before he was summoned to take command of the army of Philip in Spain, and there he won his last victories, crowning his work with the battle of Villaviciosa. Before the end of the war he died suddenly at Vinaros on the 11th of June 1712. Vendôme was one of the most remarkable soldiers in the history of the French army, and second only to Villars amongst the generals of France of the 18th century. He had, besides the skill and the fertile imagination of the true army leader, the brilliant courage of a soldier. But the real secret of his uniform success was his extraordinary influence over his men.

VENDÔME, a town of north-central France, capital of an arrondissement in the department of Loir-et-Cher, 22 m. N.W. of Blois by rail. Pop. (1906) town, 7381; commune, 9804. Vendôme is situated on the Loir, which here divides into numerous arms intersecting the town. On the south it is overlooked by an eminence on which stand ruins of the castle of the counts of Vendôme, dating in part to the 11th century. The abbey-church of the Trinity (12th to 15th century) has a fine façade in the florid Gothic style. The belfry, surmounted by a stone steeple, stands isolated in front of the church; it belongs to the middle of the 12th century, and is one of the finest examples of Transition architecture. Abbey buildings of various periods lie round the church. The church of La Madeleine (15th century) is surmounted by a stone spire, an indifferent imitation of that of the abbey. The fine tower of St Martin (16th century) is all that remains of the church of that name. The town hall occupies the old gate of St George; its river front is composed of two large crenelated and machicolated towers, connected by a pavilion. The ancient hospital of St Jacques afterwards became a college of the Oratorians, and now serves as a lycée for boys; the charming chapel, dating from the 15th century, in the most florid Gothic style, is preserved. The town has a well-known archaeological and scientific society, and possesses a library with more than three hundred MSS., and a museum, mostly archaeological, in front of which stands a statue of the poet Ronsard. There is also a statue of Marshal Rochambeau, born at Vendôme in 1725. There are some interesting houses of the 15th and 16th centuries. Vendôme has a sub-prefecture and a tribunal of first instance. The river supplies motive power to flour-mills, and the town manufactures gloves, paper and carved mouldings, and carries on tanning and nursery-gardening together with trade in butter and cheese.

Vendôme (*Vindocinum*) appears originally to have been a Gallic oppidum, replaced later by a feudal castle, around which the modern town arose. Christianity was introduced by St Bienheuré in the 5th century, and the important abbey of the Trinity (which claimed to possess a tear shed by Christ at the tomb of Lazarus) was founded about 1030. When the reign of the Capetian dynasty began, Vendôme was the chief town of a countship belonging to Bouchard, called "the Venerable," who died in the monastery of Saint-Maur-des-Fossés in 1007. The succession passed by various marriages to the houses of Nevers, Preuilly and Montoire. Bouchard VII., count of Vendôme and Castres (d. *c.* 1374), left as his heiress his sister Catherine, the wife of John of Bourbon, count of la Marche. The countship of Vendôme was raised to the rank of a duchy and a peerage of France for Charles of Bourbon (1515); his son Anthony of Bourbon, king of Navarre, was the father of Henry IV., who gave the duchy of Vendôme in 1598 to his natural son Caesar (1594–1665). Caesar, duke of Vendôme, took part in the disturbances which went on in France under the government of Richelieu and of Mazarin, and had as his sons Louis, duke of Vendôme (1612–1669), who married a niece of Mazarin, and Francis, duke of Beaufort. The last of the family in the male line (1645–1712) was Louis XIV.'s famous general, Louis Joseph, duke of Vendôme (*q.v.*). The title of duke of Vendôme is now borne by Prince Emmanuel of Orleans, son of the duke of Alençon.

See J. de Pétigny, *Histoire archéologique du Vendômois* (2nd ed., 1882).

VENEER, a thin layer of wood, ivory, pearl or other material of high decorative value fixed to a poorer surface by glue or other adhesive to improve its appearance. Wood veneers are exceedingly common: only the best woods are used and the layer may be as thin as paper—a circumstance due to improvements in the machinery for cutting the logs. The surface to which the veneer is to be attached is prepared perfectly smooth, a film of glue applied, and then the veneer laid on. It is now ironed perfectly flat, all superfluous glue being pressed out, and then allowed to dry in a press. The surface is now ready for polishing.

VENER [*Wener* or *Väner*; often written, with the addition of the definite article, *Venern*], the largest lake in Sweden and the third largest in Europe. It has an area of 2149 sq. m.; a maximum length of 87 m.; an extreme breadth of 44 m.; a maximum depth of 292 ft.; and an altitude above sea-level of 144 ft., though the surface sometimes rises as much as 10 ft. or more, for the lake is the recipient of the waters of numerous streams, the largest being the Klar, which drains the forests of Vermland and Kopparberg to the north. It is drained by the Göta river southward to the Cattegat. It is divided into two basins by two peninsulas and a group of islands, the western half being known as Lake Dalbo. The northern shores are high, rocky and in part wooded, the southern open and low, though isolated hills occur, such as the Kinnekulle (988 ft.), an abrupt hill exhibiting a remarkable series of geological strata. Several islands fringe this shore; of these Leckö has a fine medieval castle. This lake and Lake Vetter contain degenerate species of marine fauna, left after the retreat of the sea in which both were formerly included.

By means of the Dalsland Canal from Köpmannabro, midway on the west shore of Dalbo, the lake, which is the scene of a busy traffic in timber, iron and agricultural produce, has communication with Fredrikshald in Norway; and it is traversed from Venersborg on the south to Sjötorp on the east by the Göta (*q.v.*) Canal route. The principal lake-ports are—on the north Karlstad (*q.v.*) and Kristinehamn, with iron-works and tobacco factory; on the east Mariestad, chief town of the district of Skaraborg, taking its name from the queen of Charles IX. (1599–1611); on the south Lidköping, near the Kinnekulle, and Venersborg at the outflow of the Göta, with its old bridge and canal of the 17th century, a museum, and iron foundries, tanneries and match and paper factories.

VENERABLE (Lat. *venerabilis*, worthy of reverence, *venerari*, to reverence, to worship, allied to *Venus*, love; the Indo-Germ. root is *wen-*, to desire, whence Eng. "win," properly to struggle for, hence to gain), worthy of honour, respect and reverence, especially a term applied to dignified or honourable age. It is specifically used as a title of address given to archdeacons in the Anglican Church. It was naturally a term of respectful address from early times; thus St Augustine (*Epist.* 76, 88, 139) cites it of bishops, and Philip I. of France was styled *venerabilis* and *venerandus* (see Du Cange, *Gloss.* s.v. *Venerabilitas*). In the Roman Church the granting of the title "venerable" is the first step in the long process of the canonization of saints (see CANONIZATION).

VENEREAL DISEASES (from "venery," *i.e.* the pursuit of Venus, the goddess of love), a general term for the diseases resulting from impure sexual intercourse. Three distinct affections are included under this term—gonorrhoea, local contagious ulcers, known as chancres, and syphilis. At one time these were regarded as different forms of the same disease. They are, however, three distinct diseases, due to separate causes, and have nothing in common except their habitat. The cause in each case is a definite specific virus, a micro-organism. In the case of gonorrhoea the virus attacks the mucous membranes, especially that of the urethra, the vagina and the uterus. Chancres attack the mucous membranes and the skin. In syphilis the whole system comes under the influence of the poison.

Though these three affections are generally acquired as the result of impure sexual intercourse, there are other methods of contagion, as, for example, when the accoucheur is poisoned whilst delivering a syphilitic woman, the surgeon when operating on a syphilitic patient, the wet-nurse who is suckling a syphilitic infant, and so on. An individual may be attacked by any one or any two of the three, or by all at the same time, as the result of one and the same connexion. But they do not show themselves at the same time. In other words, they have different stages of incubation. In gonorrhoea the disease appears very rapidly. So also in the case of the soft chancres, the first symptoms commencing as a rule three or four days after inoculation. It is different, however, with syphilis, the period of incubation being twenty-eight days, though it may be much longer. The length of the period of incubation, therefore, is of great diagnostic help in the case of syphilis.

For many years the term "venereal disease" was used very loosely, though the writers before the year 1786 had a tolerably clear idea that three distinct diseases were included under the term: the lues venerea, now called syphilis, gonorrhoea, and a condition leading to bubo and associated with a multiple chancre which is known at the present day as "soft sores." John Hunter, as the result of an unfortunate experiment, taught that there was but a single venereal poison which manifested itself in different ways. It took the French school many years of hard work to show that the poison of syphilis was distinct from that producing a soft sore, and that the virus of a soft sore was incapable, when pure, of causing gonorrhoea.

The evidence brought forward by Ricord, by Lancereaux and by Fournier was convincing. It has been confirmed by bacteriology, and it has happened by a remarkable coincidence that the truth of the French teaching about syphilis was first established on the firm basis of experiment in France itself, when Professor Metchnikoff at the Institut Pasteur in Paris gave in his adherence to Schaudinn's work, which showed that the *Spirochaeta pallida* germ was the cause of the disease.

A. *Gonorrhoea.*

Gonorrhoea is a specific inflammation of the mucous membrane of the urethra and other passages, by the reception into it of germs known as diplococci (διπλόος, double; κόκκος, berry—the germs being double, like the halves of a walnut). After the illustrious discoverer, the germ is often spoken of as the gonococcus of Neisser. Gonorrhoea is apt to be a very serious disease, and it sometimes ends fatally.

The germs find entrance during coitus and multiply at enormous rate, spreading to all the glands and crevices of the membrane, and setting free in their development a toxin which causes great irritation of the passage with inflammation and swelling. They remain quietly incubating for three or four days, or even longer; then acute inflammation comes on, with profuse discharge of thick yellow matter, with much scalding during micturition, and there may be so much local pain that it is difficult for the person to move about. Microscopic examination of the discharge shows abundant pus corpuscles and epithelial cells from the membrane, together with swarms of diplococci (gonococci).

The inflammatory process may extend backwards and give rise to acute prostatitis (see PROSTATE GLAND), with retention of urine; to the duct of the testes and give rise to acute epididymitis (swollen testicle); and to the bladder, causing acute cystitis. It may also cause local abscesses, or, by irritation, set up crops of warts.

The treatment of acute gonorrhoea is best carried out if the patient can lie up for a while. He must avoid all fermented drinks and rich foods, and sexual and other excitement, and he should drink freely of such things as barley-water, in order to dilute, and lessen the irritation of, the urine. Hot baths are comforting. Laxatives should be freely given. The urethra should be frequently washed out with a warm solution of permanganate of potash, a grain to the pint, and, later, a weak solution of one of the zinc or silver salts may be used as an injection.

Capsules of copaiba or oil of sandalwood, and a paste of cubebs pepper, have a beneficial influence, and, later, if the man is depressed, quinine and iron will be found useful.

In ten days or a fortnight the inflammation gradually subsides, a thin watery discharge remaining which is known as *gleet.* But inasmuch as this discharge contains gonococci it may, though scarce noticeable, set up acute specific inflammation in the opposite sex.

In the case of the female the inflammation is apt to extend to the uterus and along the Fallopian tubes, perhaps to give rise to an abscess in the tube (salpingitis) which, bursting, may cause fatal peritonitis.

A lingering gleet may be due to the presence of a definite ulceration in the urethra, as shown by examination with a slender tube illuminated by electricity—the endoscope. The ulcer having been induced to heal by the application of a nitrate of silver lotion, all discharges cease. Chronic inflammation is necessarily associated with the formation of interstitial fibrous tissue, and the contraction of this new formation causes narrowing of the urethra, or stricture. Thus gleet and stricture are often associated, and the occasional passage of a large bougie may suffice to cure both. Often, however, a stricture of the urethra proves rebellious in the extreme, and leads to diseases of the bladder and kidneys which may prove fatal.

One of the most important points in the management of a case of gonorrhoea is to prevent all risk of the septic discharge coming into contact with the eye. It sometimes happens that the patient inadvertently introduces the germs into his own eye by his finger, or that his eye, or the eye of some member of the household, becomes inoculated by the use of an infected towel. If this happen, prompt and energetic measures must be taken to save the eye.

If so be that at the time of delivery a woman be the subject of gonorrhoea, there is great probability of the eyes of the infant being affected. The symptoms appear on the third day after birth, and the disease may end in complete blindness. The name of the disease is *ophthalmia neonatorum* (see BLINDNESS).

By the term *gonorrhoeal rheumatism* it is implied that the gonococci have been carried by the blood stream to one or more joints in which an acute inflammation has been set up. It is apt to occur in the third week of the disease, and it may end in permanent stiffness of the joints or in abscess.

In rare cases the germs find their way to the pleura or pericardium, setting up an inflammation which may even end fatally.

For a man to marry whilst there is the slightest risk of his still being the subject of gonorrhoea would be to subject his wife to the probability of infection, ending with chronic inflammation of the womb or of septic peritonitis. Yet it is often extremely difficult to say when a man is *cured.* That there is no longer any discharge does not suffice to show that he has ceased to be infective. Nothing less than repeated examinations of the urethral mucus by the microscope, ending in a negative result, should be accepted as evidence of the cure being complete. And these examinations should be made after he has returned to his former ways of eating, drinking and working.

B. *Local Contagious Ulcers.*

Chancroid, *soft chancre* or *soft sore* is so named in contradistinction to the Hunterian sore of syphilitic infection, the one characteristic of which is its hardness. The soft chancre is a contagious ulcer of the genitals, due to the inoculation of a distinct form of micro-organism, the bacillus of Ducrey; and, provided that the specific germ of syphilis is not inoculated at the same time, the chancre is not followed by constitutional affection. In other words, the disease is purely local, and if some of the discharge of one of these ulcers is inoculated on another part of the body of the individual a sore of an exactly similar nature appears. This reproduction of the sore can be done over and over again on the same individual.

always with the same result. But in the case of the Hunterian sore, inoculation of the individual from the primary sore gives no result, because, as explained below, the constitutional disease has rendered the individual proof against further infection. The soft sore is often multiple. It makes its appearance about three days after the exposure, and as it increases in size free suppuration takes place. It is often of about the size of a silver threepence. Its base remains soft. In individuals broken down in health, the ulceration is apt to extend with great rapidity, and is then spoken of as *phagedaenic*.

Just as an individual may contract syphilis and gonorrhoea at the same connexion, so also he may be inoculated simultaneously with the bacilli of the soft chancre and the spirochaete of syphilis. In this case the soft chancres may make their appearance, as usual, within the first three or four days, but though passing through the customary stages they may refuse quite to heal, or, having healed, they may become indurated in the second month, constitutional symptoms following in due course.

The virulence of soft sores being due to the presence of harmful germs, the surface of the sores should be touched with pure carbolic acid, which has the effect of destroying the germs and converting the sores into healthy ulcers. Or the chancres may be treated by the application of lint soaked in weak carbolic lotion. If the sore happens to be under a tight prepuce, and the germs are of great activity—as is apt to happen in such a case—ulceration may extend with extreme rapidity. It is advisable, therefore, to remove or to lay open the prepuce, in order that the sores may be effectively dealt with.

Bubo.—The bacilli from the soft sore are apt to find their way into the lymphatic vessels, and so to reach the glands in the groin, when they set up destructive inflammation. Under the influence of rest the inflammation may subside, but if it continues and suppuration threatens, the gland had better be laid open and scraped out. If a speck of the contents of the abscess be inoculated on to the skin, a soft chancre is again produced.

C. *Syphilis.*

The cause of syphilis, whether inherited or acquired, is the presence in the blood and tissues of the same organism, which can be demonstrated in the various secondary lesions, in the blood and in the internal organs. The name of the germ is *Spirochaeta pallida*;[1] it is a protozoon of spiral form, from 4 to 20 μ in length and $\frac{1}{4}$ μ in diameter, with a flagellum at either extremity. It possesses motility of three kinds—a lashing, a corkscrew and a to-and-fro movement. It stains pale pink with Giemsa's fluid. At the time of writing (1910) it has not been found practicable to make an artificial cultivation of the spirochaete. But it may generally be found in primary and secondary syphilitic lesions by the aid of a $\frac{1}{12}$ in. oil-immersion lens—and abundant patience. The pale, spiral, hair-like germ is also found in children who inherit syphilis. Inoculations of the spirochaete in monkeys have produced the characteristic primary (Hunterian) sores, which have proved infective to other monkeys. And in the reproduced primary sores, as also in the secondary lesions following them, the same specific micro-organism has been demonstrated.

Syphilis is an infective fever, and its life-history may well be compared with that of vaccinia. A child is vaccinated on the arm with vaccine lymph—for two or three days nothing is observed; but on the fourth day redness appears, and by the eighth day a characteristic vaccine vesicle is formed, which bursts and sets free a discharge which dries into a scab. If on the eighth day the clear lymph in the vesicle is introduced at another point in the child's skin, no characteristic local effect follows. The system is "protected" by the previous inoculation; this protection will last for some years, and perhaps for life. There is, then, exposure to a poison; its introduction locally; a period of incubation; a characteristic appearance at the seat of inoculation; a change in the constitution of the individual, and protection for a variable period. So with syphilis. The syphilitic poison is introduced at the seat of an abrasion either on the genital organs or on some other part of the surface of the body. The poison lies quiescent for a variable period. The average period is four weeks. A cartilaginous, button-like hardness appears at the seat of inoculation. If this is irritated in any way, an ulceration takes place; but ulceration is an accident, not an essential. From the primary seat the system becomes infected. The virus, passing along the lymphatic vessels, attacks the nearest chain of lymphatic glands. If the original sore is in the genital organs, the glands in the groin are first attacked; if in the hand, the glands of the elbow or armpit; if on the lip, the glands below the jaw. The affected glands are indurated and painless; they may become inflamed, just as the primary lesion may, but the inflammation is an accident, not an essential. In due course the poison may affect the whole glandular system. The body generally is so altered that various skin eruptions, often symmetrical, break out. Any irritation of the mucous membrane is followed by superficial ulcerations, and in the later stages of the disease skin-eruptions, scaly, pimply, pustular or tuberculous in type, appear. These eruptions do not itch. The individual is as a general rule protected against a second attack of syphilis, although there have been rare cases recorded in which individuals have been attacked a second time. In weakly people, in severe cases, or in cases that have not been properly treated by the surgeon, syphilitic deposits termed gummata are formed, which are very apt to break down and give rise to deep ulcerations. Gummata may attack any part; the skin, muscles, liver and brain are the favourite sites.

It by no means follows that because the infecting sore is small, unimportant or quickly healed, the attack, of which the sore is the first (*primary*) symptom, will be mild. The most serious train of symptoms may follow the healing of a primary sore which has been so unimportant as scarcely to have attracted the attention of the individual, or actually to have escaped notice. Indeed, it not infrequently happens that the most serious forms of secondary or tertiary symptoms succeed a sore which was regarded as of such trivial nature that the individual declined to submit himself to treatment, or quickly withdrew himself from it to enter a fool's paradise. The advisability of ceasing from treatment should always be determined by the surgeon, never by the patient; mercurial treatment must be continued long after the disappearance of the secondary eruptions. It is the *disease* which the surgeon has to cure, not the *symptoms*. The patient is apt to think only of the symptoms.

"Is the disease curable?" This is the question constantly put by the patient on his coming for treatment. The answer is: "Yes; beyond doubt." But the individual must be made to understand the necessity of his submitting himself trustfully and patiently to a prolonged course of treatment. A second question is as to whether, in the course of the disease, his hair will fall out, his body will be covered with sores and his face with blotches, and if his bones will be attacked. Here, again, the answer will be that prompt submission to treatment will render all such calamities extremely improbable. Another question often put is as to whether the disease is contagious or infectious. Obviously, if a man has a primary sore or a secondary eruption upon the lip or tongue he should use his own glass, cup or spoon, and should refrain from kissing any one. If due care thus be taken no danger is likely to ensue.

The *diagnosis* of syphilis is often difficult. The first appearance of the sore about four weeks after exposure to the risk of infection, its hardness, the indolent enlargement of the associated lymphatic glands, and the occurrence of rash or of sore throat, are all helpful. But when the primary sore occurs on the finger, the face or, indeed, in any extra-genital region, it is apt to be lacking in the usual characteristics, and so the diagnosis may for a while be missed. In the case of doubt, the blood of the patient should be submitted to the delicate test known as the Wassermann reaction.

The General Treatment of Syphilis.—It is impracticable to lay down a hard and fast line for the treatment of the disease, for no two individuals are exactly alike, neither does the disease follow a strict path in all cases. But experience has amply shown that in the early stages of the disease, mercury, at least for the present, is the only drug on which reliance can be placed. Guaiacum was at one time extensively used, and somehow or another sarsaparilla acquired a bubble reputation; but the practical surgeon of to-day ignores these drugs in the treatment of syphilis. Still, mercury must be prescribed with great judgment. For a man worn out by alcoholic or other excesses, or with health broken down by tuberculosis or other exhausting disease, mercury must be given with great caution. In times past, its reckless administration until profuse salivation was set up, or until the teeth fell out and the very jawbones became diseased, deservedly brought the mercurial treatment into disrepute. "Better the disease than the remedy," said public opinion, and not without reason. But this miscarriage of treatment is absolutely a thing of the past. Before placing a patient under mercurial treatment it ought to be seen that there is no unwholesome condition of his gums, and that his teeth are put in a satisfactory state; unless this is done, the administration of small doses of mercury may have the effect of producing salivation, and, in consequence, a temporary cessation of the treatment. In any case the gums must be watched, and the treatment stopped if tenderness occurs.

There are several ways of giving mercury: (*a*) by the mouth; (*b*) by rubbing a mercurial ointment into the skin; (*c*) by injection into the muscles; (*d*) by inhalation of mercurial vapour. Inunction is especially suited for those whom mercury given by the mouth causes diarrhoea or other disturbance; in a private house, however, it is found "dirty" and objectionable.

The fumigation-treatment is carried out by seating the naked man on a cane-bottomed chair and covering him over with a blanket; calomel being volatilized, its fumes are carried under the blanket along with steam.

Treatment by intra-muscular injections is increasing in popularity, but in carrying it out, great care must be taken that no septic germs are introduced. The preparation of mercury is given in solution or mixed with oil, and is usually injected about once a week into the muscles of the buttock or loin. The "grey oil," which is much used for injections, consists of finely divided metallic mercury in

[1] From χαίτη, long hair, on account of the waving, hair-like appearance of the germ.

some fluid fat. Calomel is also used suspended in olive oil. After a few months of weekly injections there should be some weeks of rest from treatment.

But the most usual, and, perhaps, the most satisfactory method of administering mercury is by the mouth, in the form of pills or mixtures. The pills generally contain metallic mercury finely divided, as in "blue pill" and as in pills made of "grey powder," or as calomel, or some other salt of mercury, such as the bichloride or tannate. The preparation given in a mixture is usually a solution of perchloride of mercury.

Whilst the individual is undergoing mercurial treatment his diet must be regulated. Plain meat, roast and boiled, and vegetables which cannot cause indigestion or diarrhoea, will form his chief food. Spirits and liqueurs should be absolutely forbidden, but a glass or two of wholesome wine or beer may occasionally be allowed. If there is any secondary eruption of the tongue, mouth or throat, smoking must be forbidden. The dress must be warm, and there should be no exposure to extremes of cold or heat, nor should excessive work or amusement be undertaken. Briefly, it may be said that the subject of syphilis should live low and think high. It has been said by an English physician who delighted in epigrams, "Syphilis once, syphilis ever"; but this is not true. If the individual places himself unreservedly and continuously under the treatment of a trustworthy practitioner, he may confidently look forward to a cure; and, if so be that he is eventually married, may depend upon his children showing no sign of his unfortunate infection.

Unlike whooping-cough, smallpox or pleurisy, syphilis is not a disease which, left untreated, cures itself in the course of time. Syphilis is a disease which peculiarly calls for treatment, and that treatment, to be effectual, must be prolonged. To promote the healing of an ulcer, or to get rid of a cutaneous eruption, the result of syphilis, is not to treat syphilis. It is merely to free the patient of a symptom of the disease. To cure syphilis—and the disease is curable—the treatment must be patient and prolonged. And it must be for the surgeon to say to the individual that he may consider himself as cured, not for the patient to take upon himself the assumption that, because no secondary or tertiary symptoms have been seen for a certain number of months, he is cured.

In the midst of the uncertainties which surround the subject of syphilis, the question sometimes arises as to whether the treatment by mercury, for instance, is of the importance which is ascribed to it. Two instances may be given in proof of its undoubted value. First, a woman who has been infected and never properly treated, becomes pregnant, and though, perhaps, showing signs of good health in every other respect, has a miscarriage; pregnancy and miscarriage follow each other at short intervals, four, six or eight times. Then, at last, she is put upon mercurial treatment, and, going to her full time, bears a healthy infant. Second, an infected but healthy-looking woman, who has not been properly treated, produces a child who, in the course of a few weeks, becomes shrivelled and wan. His food does him no good, and daily he becomes more miserable. At last some mercurial ointment is spread upon his "binder," and he quickly becomes healthy and happy, and, in due course, if the treatment is persevered in, is entirely cured.

When should the Treatment of Syphilis be begun?—The answer to this important question is: "As soon as the disease is diagnosed." As soon as it is seen that the primary sore is hard, and that the glands in anatomical association with it are swollen, mercury should be administered. It may not prevent the outbreak of the secondary symptoms, but it may greatly modify them. But if a surgeon is in doubt as to whether a sore is truly an infecting one, he should wait before condemning the individual as syphilitic, and placing him under the necessity of submitting himself to perhaps a two years' treatment, which, after all, may not have been necessary. Time would quickly clear up doubt.

Abortive Treatment.—When it is remembered that the germs of syphilis have been incubating at the seat of inoculation for a month, more or less, before the primary sore or chancre makes its appearance, it may be taken for granted that the removal of the sore by wide dissection, or its destruction by cautery, will not prevent the occurrence of secondary symptoms. For during those weeks the germs were finding their way into the lymphatics and the blood vessels and were producing a general infection.

When the disease has undergone a sufficient treatment by mercury, or when a patient presents himself with lesions which denote the fact that the disease has passed into the tertiary stage, a solution of iodide of potassium is given in combination with that of perchloride of mercury, or the iodide is given by itself. In these conditions the effect of the potassium salt is often most remarkable. It is a drug of the greatest value, and, recognized as such, is apt to be found an important ingredient in popular "blood mixtures." If given, however, in doses larger than can be borne by the patient, its poisonous effects are manifested by a metallic taste, by watering of the eyes and by the breaking out on the back and shoulders of scattered pimples.

Thus, mercury in some form is the recognized and proper treatment for syphilis in the secondary stage, and iodide of potassium in the tertiary. And, for as much as one cannot say where the secondary stage ends and the tertiary begins, it is a common practice to combine the mercuric with the potash salt in the treatment of certain phases of the disease.

In 1910 attention was hopefully directed towards Professor Ehrlich's treatment of syphilis by a complex preparation of arsenic, conveniently spoken of as "606."

Gummata.—The most characteristic form of the generalized syphilitic infection, which may not manifest itself for several years after the reception of the virus, is a new growth in various organs—the liver, testes or brain, the muscles (tongue and jaw-muscles especially), the periosteum, the skin and the lungs. The deposits are called gummata from the tenacious appearance of the fresh-cut surface and of the discharge oozing from it. The structure consists of small round cells among thin fibres; it closely resembles granulation-tissue, only that the cells are smaller and the intercellular substance (fibres) denser. Molecular death, or necrosis, overtakes this ill-organized, new formation at various central points, owing to the inadequacy of the blood supply. One remarkable feature of the process is the overgrowth of cells in the inner coat of the arteries within the affected area, which may obliterate the vessel. Gummata, and the ulcers left by them, constitute the *tertiary* manifestations of syphilis.

In a large proportion of cases only the secondary symptoms occur, and not the tertiary, the virus having presumably exhausted itself or been destroyed by treatment in the earlier manifestations.

Inherited Syphilis.—In the syphilis of the offspring it is necessary to distinguish two classes of effects—there are the effects of general intra-uterine mal-nutrition, due to the placental syphilis of the mother; and there are the true specific effects acquired by inheritance from either parent and conveyed, along with all other inherited qualities, in the sperm-elements or in the ovum. These two classes of effects are commingled in such a way as not to be readily distinguished; but it is probable that the ill-organized growth of bone, at the epiphysial line in the long bones (sometimes amounting to suppuration), and on the surfaces of the membrane-bones of the skull (*Parrot's nodes*) is a result of general placental mal-nutrition, like the corresponding errors of growth in rickets. The rashes and fissures of the skin, the snuffles and such-like well-known symptoms in the offspring are characteristic effects of the specific taint; so also the peculiar overgrowth in the liver, the interstitial pneumonia alba of the lungs and the like. As in rickets, it is in many cases some months after birth before the congenital syphilitic effects show themselves, while other effects come to light during childhood and youth.

It must be remembered that the moist eruptions and ulcerations about the mouth and anus of the infant, as well as the skin affections generally, are charged with the spirochaetes and are highly contagious.

From the second to the sixth year there is commonly a rest in the symptoms that are regarded as characteristic, but the tibiae may become thickened from periostitis, or a joint may become swollen and painful, and resolve under mercurial treatment.

The characteristic physiognomy gradually manifests itself if the child is not treated with mercury—the flattened nose, the square forehead, the radiating lines from the mouth, the stunted figure and pallid face. During the second dentition, the three signs, as pointed out by Jonathan Hutchinson, may be looked for—the notched incisor teeth of the upper jaw, interstitial corneitis and syphilitic deafness. Perforation of the soft or hard palate may occur, and ulcerations of the skin and cellular tissue. Destruction of the nasal bones, caries of the forehead and skull, of the long bones, may also take place.

Colles' Law.—A woman giving birth to a syphilitic infant cannot be inoculated with syphilis by the infant when she is suckling it; in other words, though the mother may have shown no definite signs of syphilis, she is immune; whereas the syphilitic infant put to the breast of a healthy woman may inoculate her nipple and convey syphilis to her. This is known as Colles' Law, and it is explained by the theory that, the mother's blood being already infected, her skin is proof against a local cultivation of germs in the form of a Hunterian sore.

Syphilis and Marriage.—The question as to how soon it would be safe for a person with secondary syphilis to marry is of extreme importance, and the disregard of it may cause lasting mental distress to the parent and permanent physical injury to the offspring. A man who finds himself to be the subject of secondary syphilis when he is engaged to be married would do well honourably to free himself from responsibility. But should a person who has been under regular and continuous treatment desire to marry, consent may be given when he has seen no symptoms of his disease for two full years. But even then no actual promise can be made that his troubles are at an end.

The *transmission of syphilis to the third generation* is quite possible, but it is difficult of absolute proof because of the chance of there having been intercurrent infection of the offspring of the second generation.

VENETI, the name given to two ancient European tribes. (1) A Celtic people in the N.W. of Gallia Celtica, whose territory corresponded roughly to the department of Morbihan. They were the most powerful maritime people on the Atlantic and carried on a considerable trade with Britain. Their name still remains in the town of Vannes. In the winter of 57 B.C., with some of their neighbours, they took up arms against the Romans, and in 56 were decisively defeated in a naval engagement, details of which are given in Caesar's *Bell. Gall.* iii. and Dio Cassius xxxix. 40–43.

For criticisms of these narratives, and a discussion of the question of the scene of operations, see T. R. Holmes, *Caesar's Conquest of Gaul* (1899), pp. 205, 663, 674, and for the extent of their territory, p. 509.

(2) The inhabitants of a district in the north of Italy (also called Ἐνετοί, Heneti, by the Greeks). The extent of their territory before their incorporation by the Romans is uncertain. It was at first included in Cisalpine Gaul, but under Augustus was known as the tenth region of Italy (Venetia and Histria). It was bounded on the W. by the Athesis (Adige), or, according to others, by the Addua (Adda); on the N. by the Carnic Alps; on the E. by the Timavus (Timavo) or the Formio (Risano); on the S. by the Adriatic Gulf. From the earliest times the Veneti appear to have been a peaceful people, chiefly engaged in commercial pursuits. They carried on an extensive trade in amber, which reached them overland from the shores of the Baltic. They were especially famous for their skill in the training and breeding of horses, attributed to their stay in Thrace, whence they brought the cult of Diomede into their Italian home. Homer (*Il.* ii. 85) speaks of the Paphlagonian Heneti as breeders of "wild mules," and their fondness for horses is regarded as a proof of their descent from the "horse-taming" Trojans. Dionysius, tyrant of Syracuse, who assisted them to repel the attacks of the Liburnian pirates, is said to have kept a stud in their country. Herodotus mentions a curious marriage custom, which seems of Eastern origin. Once a year the marriageable maidens of a village were collected together. Each young man chose a bride, for whom he had to pay a sum of money in proportion to her beauty. The sums thus obtained were used by the public officials to dower the less beautiful and thus afford them the chance of obtaining a husband. According to the pseudo-Scymnus of Chios (*Periegesis*, 400) the Veneti were fond of wearing black, a custom even now prevalent amongst them. They were a flourishing and wealthy people, and noted for their uprightness and morality.

The first historical mention of the Veneti occurs in connexion with the capture of Rome by the Gauls, whose retreat is said to have been caused by an irruption of the Veneti into their territory (Polybius ii. 18). At the request of the Romans they rendered them assistance in their wars against the Gauls north and south of the Po, and ever afterwards remained their loyal allies. Some time during the Second Punic War they passed, not by right of conquest but by force of circumstances, under Roman rule. At first they possessed complete autonomy in internal administration; in 89 Gnaeus Pompeius Strabo bestowed upon them the *jus Latinum*; they probably obtained the full franchise from Caesar at the same time as the Transpadane Gauls (49). Under the Empire Venetia and Istria were included in the tenth region of Italy, with capital Aquileia. Down to the time of the Antonines the country enjoyed great prosperity, which was interrupted by the invasion of the Quadi and Marcomanni and a destructive plague. From that time it was devastated at intervals by the barbarians—by the Alamanni, Franks and Juthungi in 286; by the Goths under Alaric (beginning of the 5th century); by the Huns under Attila (452), who utterly destroyed Aquileia and several other cities. Under Theodoric the Great (ruler of Italy from 493–526) the land had rest, and in 568 was occupied by the Lombards. The most important river of Venetia was the Athesis (Adige); its chief towns Patavium (see PADUA), Aquileia (*q.v.*), Altinum (Altino), Belunum (Belluno, still a considerable town).

Language.—We have nearly 100 inscriptions which record the language spoken by the tribe in pre-Roman days, the bulk of which we owe to the admirable and devoted excavations carried out at Este since 1890 by Prof. A. Prosdocimi and Sign. A. Alfonsi. But a not unimportant number have also come to light at Verona and Padua, and at different points along the great North and South route of the Brenner Pass, especially at Bozen; and there are a few more scanty and scattered monuments in the Carinthian Alps now preserved chiefly in the Museums at Klagenfurt and Vienna (the *K.K. Naturhistorisches Museum, Ethnographische Abteilung*). All but a few of these Venetic inscriptions were seen and transcribed by the present writer in the spring of 1908, and their texts with a careful collection of the local and personal names of the district made by Miss S. E. Jackson will appear as the first part of "The Pre-Italic Dialects" in the *Proceedings of the British Academy.*

The alphabet of the inscriptions, in all its varieties, is probably (in spite of Pauli, *Die Veneter*, p. 226, whose judgment seems somewhat arbitrary) either derived from or at least influenced by some form of the Etruscan alphabet, since it not merely coincides with that alphabet in several characteristic signs, such as the use of the compound symbol *vh* (𐌄𐌅) with the value of *f*, but lacks the symbols for the mediae B D G. These, or the sounds which had descended from them in Venetic, were represented by using symbols which in the Western Greek alphabets denoted kindred sounds; 𐌆 *z* where we should expect *d* (*zoto*, "he gave"), Φ φ where we should expect *b* (φohιιos, "Boius"), Ψ (*i.e.* χ) where we should expect *g* (·ε·χo, "ego"). But though we find the symbols in positions where they correspond to the mediae in kindred languages, it is uncertain what the precise variety of sound which they denoted was; thus, for example, Venetic ·ε·χo, is certainly equivalent to the Latin *ego*, but we cannot be certain that the sound of the two words was precisely the same. The symbol for θ is not used to denote *d* (since that is represented by *z*). In the inscriptions of Padua and Verona the sign is O and seems there to denote some variety of sound closely akin to *t*; the word which at Padua and Verona is written *·e·kupe-θari·s·* (probably meaning "charioteer") appears as *ecupetaris* in Latin alphabet in an inscription published by Elia Lattes ("Iscrizioni Inedite Venete ed Etrusche," *Rendiconti del R. Ist. Lomb. di Sc. e Lett.*, Serie II. vol. 34, 1901). The full Venetic alphabet at its best period is preserved for us on several curious and interesting dedicatory objects found at Este, which were offered to the goddess of the place called *Rehtia*, a name obviously equivalent to Latin *Rectia*, some of whose prerogatives, to judge from the long nails which are offered to her, frequently accompanied by small wedges, would seem to have been those of the goddess whom Horace calls Necessitas (*Odes*, i. 35, 17). The offerings in question are thin bronze plates of whose surface the greater part is covered by alphabetic signs, with an inscription stating that such and such a worshipper makes an offering of the plate to the Goddess Rectia. Besides the letters of the alphabet in their order, these plates contain a kind of catalogue of the most common combination of letters, and although none of the plates is now completely preserved this characteristic and their general likeness to one another provide enough material to place the alphabet of Este beyond all doubt. It is written from right to left, and the alternate lines curl round so that the letters proceed in the opposite direction and stand with their feet turned towards those in the preceding line. This characteristic, technically known as "serpentine boustrophedon," with the sign for *h* (𐌇), points to some connexion with the alphabets of the East Italic ("Sabellic") inscriptions (see SABELLIC).

The alphabet of Este then, in what the archaeological remains show to have been the 4th and 3rd centuries B.C., was as follows:—

𐌀 *a*, 𐌄 *c*, 𐌅 *v*, 𐌆 *z*, 𐌇 *h*, ⊠ θ, 𐌊·*k*, 𐌋 *l*, 𐌌 *m*, 𐌍 *n*, 𐌐 *p*, M *ś*, 𐌓 *r*, 𐌔 and 𐌔 *s*, X *t*, Λ *u*, ⟐ or ⦶ φ, Ψ χ, ◇ *o*.

Pauli (*Die Veneter*, p. 229) compares it to the Western Greek alphabet as used in Elis, but it is difficult to point to any especial mark of affinity with this particular branch of the Western alphabet, while there are some marked differences, such as X instead of Elean T, ᗡ instead of Elean (prevailingly) ᚦ and R. ⚹ instead of I and ꟾ instead of the regular Western 𐌇 though the latter symbol is not quoted as occurring in Elis itself (E. S. Roberts, *Greek Epigraphy*, i. 390).

Even the few words that have already been cited from the inscriptions will have shown that the language belongs to the Indo-European group. Unfortunately the inscriptions of Este, although numerous, belong to only two classes, dedications and epitaphs; hence the forms with which they supply us, though attested by welcome repetition, are somewhat limited in number. The typical beginning for a dedication is *meχo....zona·s·to sahnateh rehtiiah*, *i.e.* "me dedit Rectiae Sanatrici," "so and so gave me to the Healing Goddess Rectia"; and sometimes the form of the verb is simply *z·o·to*. The correspondence of these two forms with the Greek middle aorist of the verb (ἔ-δοτο), and with the Latin *donare* is obvious, and the present writer is convinced, for reasons which it is impossible to state fully here, that the dots which, it will be observed, are placed on either side of the last sound of their syllable, denote the accent of the word; the most striking evidence being the coincidence in position of the dots with the place of the Greek accent on kindred words; for example, the cognomen *Lehvo·s·* on an inscription of Vicenza is clearly identical with the Latin *Laevus* and the Greek λαιϝός. These signs are altogether absent from some words, *e.g.* from the Accusative *μεχο* (presumably a proclitic) and syllables containing the letter ꟾ, whose form would make the dots a cumbrous addition. One other inscription of special linguistic interest should be cited here; it appears to be the artist's inscription of a vase of the 6th century B.C. found recently at Padua—

voθo kluθeari·s· vhaχ·s·to,.

where the first name appears to be identical with the Latin *Otho* and to explain its aspirate, and the last word appears to be the Venetic equivalent of the Latin *fecit*, but to be in the middle voice without any augment. If this interpretation be correct—and the use of ἐποίησε by Greek artists commends it strongly—the form illustrates in rather a striking way the character of the language as intermediate between Greek and Latin.[1]

In the archaeological aspect the Venetic remains are particularly interesting as representing very fully the culture of what is known as the early Iron Age, the monuments of which were discovered in the excavations at Villanova, and are now admirably exhibited in the Museum at Bologna. The earliest begin, according to the generally accepted dating, from the 11th century B.C. The remains at Este begin a very little later, but no inscriptions appear upon them until we reach the pottery of the 6th century B.C. It remains therefore to be determined whether this Venetic language was the proper speech of the people who, as it is generally supposed, brought with them the early Iron culture into Italy from north of the Alps in the 11th century B.C., or whether it was the language of the people of the soil whom they conquered. So far as the scanty linguistic evidence at present extends, in the place names and the personal names of the Ligurian and the Venetic districts, it appears to the present writer on the whole to be more in favour of the second view. This probability would become a certainty if we could accept as established the view of Professor Ridgeway and others, which identifies the authors of the early Iron culture with the Umbrians of historical times and ascribes to them the Umbro-Safine language (which with Latin constitutes the Italic division of the Indo-European languages), and which almost certainly was the language originally spoken by the patrician class at Rome (see further SABINI). Even now it must be admitted that this view possesses a high degree of probability.

The chief authority on the Venetic inscriptions published up to 1908 is Carl Pauli (*Altital. Studien*, vol. 3, "Die Veneter," Leipzig, 1891), but so far as the present writer's observation may be trusted the text which Pauli gives of the inscriptions is somewhat defective. Some were reported by Mommsen, *Die Inschriften Norditalischen Alphabets* (Zürich, 1853); the rest have been recorded in the *Notizie degli Scavi* as they appeared, by Ghirardini in the volumes for 1880 and 1888, by Prosdocimi in that for 1890. These articles contain careful accounts of the archaeological remains. (R. S. C.)

VENETIA, a territorial division of northern Italy, lying between the Alps and the Adriatic, and stretching from the frontier of Carinthia and Istria (Austria) in the north-east to the lower Po and Lombardy in the south-west. It comprises the provinces of Belluno, Padua, Rovigo, Treviso, Udine, Venice, Verona and Vicenza, and has an area of 9476 sq. m. Pop. (1881) 2,814,173; (1901) 3,192,897. The crops principally grown are maize, wheat, rice, grapes, mulberry leaves, tobacco, chestnuts, potatoes and hemp. Copper and lignite are mined, and turf is dug. The chief industries are the manufacture of woollens, cottons, silks, glass, laces, tobacco, straw-plait, paper, sugar and hemp, the breeding of silkworms, iron-founding and working, timber-cutting and shipbuilding. At Mira is a large candle factory. The peasantry suffer much from pellagra.

The territory differs much in character; the Po and other smaller rivers which fall into the Adriatic terminate in a huge and continually advancing delta which extends right along the coast, and is liable to inundation. The shore lagoons are, however, rendered healthy by the ebb and flow of the tide, which is much more considerable than elsewhere in the Mediterranean. To the north of the Po at the foot of the mountains is a fertile territory, while the mountains themselves are not productive. The chief towns in the various provinces, with their communal population in 1901, are: Belluno 19,050; total of province 214,803, number of communes 66; Padua 81,242; Monselice 11,571, Este 10,779, Piove di Sacco 10,021; total of province 444,360, number of communes, 103; Rovigo 10,735, Adria 15,711; total of province 222,057, number of communes 63; Treviso 32,793, Castelfranco Veneto 12,440, Montebelluna 10,284, Conegliano 10,252; total of province 416,945, number of communes 95; Udine 36,899, Pordenone 12,409, S. Vito al Tagliamento 10,160; total of province 614,270, number of communes 179; Venice 148,471, Chioggia 31,218, Cavarzere 16,388, Mira 12,169, Mestre 11,625; total of province 399,823, number of communes 50; Verona 73,917, Legnago 14,535; total of province 427,018, number of communes 113; Vicenza 43,703, Bassano 15,097; Schio 13,524; Arzignano 10,426, Lonigo 10,390; total of province 453,621, number of communes 123. Railway communication in Venetia is fairly good; there is a main line from Milan to Mestre (the junction for Venice) and thence to Trieste by a line near the coast, or by Treviso, Udine and Pontebba (Pontafel) into Austria. Another route into Austria, the Brenner, leaves the Milan-Venice line at Verona, which is connected with Modena (and so with central and southern Italy) by a railway through Mantua. Another main line runs from Bologna to Ferrara, Rovigo and Padua, joining the Milan-Venice line at the last-named place. Intercommunication between the main lines is secured by branch railways and steam tramways. The Po, however, forms somewhat of an obstacle, but is crossed by the main lines to Modena and Bologna near Mantua and Rovigo respectively.

The district which later bore the name of Venetia was inhabited, under the Roman Republic, by a variety of tribes—Celts, Veneti, Raeti, &c. Under Augustus, Venetia and Histria formed the tenth region of Augustus, the latter including the Istrian peninsula as far as the river Arsia, *i.e.* with the exclusion of the strip along the E. coast (Liburnia). In all directions, indeed, it extended farther than Venetia in the modern sense, being bounded on the S. by the Po and its main (north) arm, extending on the W. as far as the Adda and on the N. into a part of southern Tirol. It was thus far the largest of the regions of Italy, but possessed comparatively few towns; though such as there were, with the large territories, acquired considerable power and influence. The easiness of the Brenner pass and the abundance of communication with the sea led to the rise of such towns as Verona, Padua and Aquileia: and Milan only became more important than any of these when the German attacks on Italy were felt farther west.

When the Roman Empire fell the towns were many of them destroyed by Attila, and the inhabitants took refuge in the islands of the lagoons. It is to this that Venice owes its origin, under Byzantine protection, early in the 9th century A.D. For the gradual growth of Venetian supremacy over the whole territory, and for its subsequent history, see VENICE.

VENETTE, JEAN DE (*c.* 1307–*c.* 1370), French chronicler, was born at Venette, near Compiègne. He became prior of the Carmelite convent in the Place Maubert, Paris, in 1339, and was provincial of France from 1341 to 1366. In 1368 he was still living, but probably died within a year or two of that date. His Latin Chronicle, covering the years 1340 to 1368, was published by Achery (*Spicilegium*, vol. iii.) with the continuations of the chronicle of William of Nangis, though it has every claim to be considered as an independent work. During the years 1358 and 1359 the entries were contemporary with the events recorded; the earlier portion of the work, if it was begun as early as 1340, was subjected to revision later. Jean de Venette was a child of the people, and his sympathies were entirely with the peasants. His point of view is thus directly

[1] Some further details will be found in the Preliminary Report presented to the British Academy published in the *Athenaeum*, August 8th, 1908.

opposed to that of Froissart. His democratic sympathies led him to support Étienne Marcel, and though he returned to his allegiance to the kings of France he remained a severe critic. Jean de Venette also wrote a long French poem, *La Vie des trois Maries*, about 1347.

See Lacurne de Sainte-Palaye in *Mémoires de l'Académie*, vols. viii. and xiii.; Géraud and Déprez in *Mélanges de l'école de Rome* (1899), vol. xix.; and A. Molinier, *Les Sources de l'histoire de France* (1904), tome iv.

VENEZUELA,[1] a republic of South America, facing the Caribbean sea, and bounded E. by British Guiana and Brazil, S. by Brazil and W. by Colombia. Its boundary with Colombia is unfixed, a decision by the king of Spain, as arbitrator, in March 1891, having been rejected by Venezuela. The boundary dispute with British Guiana was settled in October 1899 by an arbitration court in Paris. The line is subject to any question between the two countries and Brazil. The boundary with Brazil was fixed by a special commission in 1880. The republic lies between lat. 1° 40′ S. and 12° 26′ N., long. 59° 40′ and 73° 31′ W., and has an area of 599,538 sq. m. according to the Venezuelan *Year Book* of 1906. This area, however, was subject to the settlement of the Colombia boundary line, and the measurement is only approximate.

Topography.—The surface of Venezuela is broken into three very irregular divisions by its mountain systems: (1) the mountainous area of the N.W. and N.; (2) the Orinoco basin with the *llanos* on its northern border and great forested areas in the S. and S.W.; and (3) the Guiana highlands. A branch of the eastern chain of the Andes enters Venezuela in the west about 7° N. lat., and under the name of the Sierra Nevada de Mérida proceeds north-eastwards towards Trieste Gulf. This branch consists of parallel chains enclosing elevated valleys, in one of which lies the town of Mérida at the height of 5410 ft., overlooked by the highest summit of the chain (Picacho de la Sierra, 15,420 ft.). The sierra contains the water-parting between the basin of the Orinoco and those of the small rivers on the north-west. Hence it may be considered to terminate where the Rio Cojedes, which drains the elevated valley in which Barquisimeto stands, after rising on its western slopes flows eastwards into the basin of the Orinoco. Beyond the Cojedes begin two parallel ranges known as the Maritime Andes of Venezuela, which stretch east and west along the coast. The valley between these two ranges is the most densely peopled part of Venezuela. Above Carácas the highest peak of the system, Silla de Carácas, rises to 8531 ft. Behind the wide bay between Cape Codera and Cumana there is an interruption in the Maritime Andes; but both ranges reappear between Cumana and the Gulf of Paria. West of the Maritime Andes low ranges (3500–5000 ft.) trend northwards from the end of the Sierra de Mérida towards the coast on the east side of the Lake of Maracaibo, while the region on the west of that lake consists of lagoon-studded lowlands. East and south of the Sierra de Mérida and the Maritime Andes the region is thinly populated and little known. It consists of two portions—a vast, hilly or mountainous area, densely wooded, in the south-east and south, and level plains in the north-west between the Orinoco and the Apuré and the mountains. The latter is known as the *llanos* of the Orinoco, a region described by Humboldt as a vast "sea of grass," with islands of wood scattered here and there. Since the time of Humboldt, however, the aspect of these plains would seem to have changed. On the occasion of Karl F. Appun's visit in 1850 trees seem still to have been comparatively rare; but a different aspect was presented when Dr P. Jonas visited the *llanos* in 1878. From the Galera, the southernmost range of hills north of the Orinoco basin, the traveller saw a vast plain thickly grown with low trees. As far as Calabozo (about one-third of the distance between the hills and the Apuré) it was now chaparros (*Curatella americana*), now mimosas, which were the prevailing feature of the landscape. But towards the south the open grass-covered spaces increased in number and area. To the south of Calabozo woods of considerable extent were seen. This change is due to the decline of horse- and cattle-rearing in the *llanos*, partly in consequence of political disturbances and partly of a murrain which broke out in 1843 among horses, mules and asses. The decline in stock-raising would also suspend the practice of burning off the dead grass to improve the new pasturage. Along the Brazilian frontier and about the sources of the Orinoco tributaries on the eastern slopes of the Andes there are extensive forests, sometimes broken with grassy *campos*. The surface of the *llanos* is almost a dead level, the general elevation varying from about 375 to 400 ft., rising almost imperceptibly to 600–800 ft. around its immediate margins. So uniform is the level over a great part of these plains that in the rainy season hundreds of square miles are submerged, and the country is covered with a network of connecting channels. When the Orinoco is reached its lower basin is contracted between the Guiana highlands and the northern sierras, and its tributaries begin to come in more nearly at right angles, showing that the margins of the actual valley are nearer and higher. About 62° 30′ the great river reaches what may be considered sea-level, and from this point numerous channels find their way across the silted-up delta plain to the sea. This region, together with that of the Guiana frontier, is heavily forested. In the extreme S. (territory of Amazonas) and S.E. the surface again rises into mountain ranges, which include the Parima and Pacaraima sierras on and adjacent to the Brazilian frontier, with a number of short spurs reaching northward toward the Orinoco, such as the Mapichi, Maraguaca, Maigualida, Matos, Rincote and Usupamo. All this region belongs to the drainage basin of the Orinoco, and rivers of large volume flow down between these spurs. Some of the culminating points in these ranges are the Cerros Yaparana (7175 ft.) and Duida (8120 ft.) in the Parima sierras near the upper Orinoco, the Sierra de Maraguaca (8228 ft.), and the celebrated flat-topped Mt Roraima (8530 ft.) in the Pacaraima sierras on the boundary line with Brazil and British Guiana. Near the Orinoco the general elevation drops to about 1500 ft. All this region is densely forested, and is inhabited only by scattered tribes of Indians.

Probably not less than four-fifths of the territory of Venezuela belong to the drainage basin of the Orinoco (*q.v.*). The Orinoco is supposed to have 436 tributaries. of which, among the largest, the Caroni-Paragua, Aro, Caura, Cuchivero, Suapure, Sipapo and Ventuari have their sources in the Guiana highlands; the Suata, Manapere and Guaritico in the northern sierras; and the Apuré, Uricana, Arauca, Capanaparo, Meta, Vichada and Guaviare (the last three being Colombian rivers) in the *llanos* and Andes. The Apuré receives two large tributaries from the northern sierras—the Guarico and Portuguesa. Apart from these, the rivers of Venezuela are small and, except those of the Maracaibo basin, are rarely navigable. The larger are the Guanipa and Guarapiche, which flow eastwards to the Gulf of Paria; the Aragua, Unare and Tuy, which flow to the Caribbean coast E. of Carácas; the Yaracui, Aroa and Tocuyo to the same coast W. of Carácas; and the Motatan, Chama, Escalante, Catatumbo, Apan and Palmar, which discharge into Lake Maracaibo. The hydrography of the region last mentioned, where the lowlands are flat and the rainfall heavy, is extremely complicated owing to the great number of small rivers and of lakes on or near the lower river courses. The deep lower courses of these streams and the small neighbouring lakes were once part of the great lake itself, which is being slowly filled by silt. The lakes of Venezuela are said to number 204. The largest are the Maracaibo (*q.v.*); El Zulia, with an area of 290 sq. m., a short distance S. of Maracaibo among a large number of lakes, lagoons and swamps; Valencia, near the city of that name, in the Maritime Andes, about 1350 ft. above sea-level, with an area of 216 sq. m.; Laguneta, in the state of Zulia; and Taciragua, a coastal lagoon in the state of Miranda. There are numerous lagoons in the *llano* districts caused by the periodical floods of the rivers, and extensive *esteros* and *cienagas*, in part due to the same causes, but these either dry up in the dry season or are greatly reduced in area.

The coast outline of Venezuela is indented with a large number of gulfs and bays, comparatively few of which, however, are open to foreign commerce. The larger indentations are the Gulf of Maracaibo, or Venezuela, which extends inland through the Lake of Maracaibo, with which it is connected by a comparatively narrow channel, and is formed by the peninsulas of Goajira and Paraguaná; the Gulf of Paria, between the peninsula of that name and the island of Trinidad; the Gulf of Coro, opening into the Gulf of Maracaibo; the Gulf of Cariaco, between the peninsula of Araya and the state of Bermúdez; the Golfo Triste, on the E. coast of the state of Lara; and the small Gulf of Santa Fé, on the northern coast of Bermúdez. Besides these there are a number of small indentations, sheltered anchorages formed by islands and reefs like that of Puerto Cabello, and estuaries and also open roadsteads, like those of La Guaira and Carúpano, which serve important ports. The islands on the coast forming part of the national territory number 71, with an aggregate area of 14,633 sq. m., according to official calculations. The largest of these is the island of Margarita, N. of the peninsula of Araya, in the vicinity of which is the island of Tortuga and several groups of islets, generally uninhabited. (A. J. L.)

Geology.—Geologically Venezuela consists of three distinct regions: (1) South of the Orinoco a great mass of granite, gneiss, pyroxenite and other crystalline rocks, continuous with that of Guiana and probably of Archean age. This mass also forms the bed of the Orinoco from its junction with the Apuré nearly to its mouth, and it probably extends northwards for some distance beneath the more recent deposits of the plain. (2) The *llanos*, covered by deposits of Quaternary or late Tertiary age. (3) The mountain ranges of the north-west and north. These ranges appear to belong to two systems. The Cordillera of Mérida is one of the

[1] The name means "little Venice," and is a modification of the name of Venecia (Venice), originally bestowed by Alonzo de Ojeda in 1499 on an Indian village, composed of pile dwellings on the shores of the Gulf of Maracaibo, which was called by him the Gulf of Venecia.

branches of the Andes, and the strike of the folds which compose it is usually from south-west to north-east. The Caribbean chain along the north coast is part of the Antillean system, and here the strike of the folds is nearly west to east or west-south-west to east-north-east. The two systems of folds meet about Barquisimeto, where the structure becomes very complex and is not thoroughly understood. The rocks of Falcón are believed by Sievers to belong to the Andean system; while the outlying peninsula of Paraguaná probably belongs, geologically, to the same massif as Goajira and the Sierra Nevada de Santa Maria in Colombia. The oldest rocks in the country are the granites, gneisses, &c., of the southern massif and the crystalline schists which form the axis of the Cordillera and the Caribbean chain. In the latter range a few Ordovician fossils have been found, but in general the oldest strata which have yielded organic remains belong to the Cretaceous system. The Cretaceous beds form a band along each side of the Cordillera and along the southern flank of the Caribbean chain, and they spread over the greater part of the provinces of Falcón and Lara. The Lower Cretaceous consists chiefly of sandstones and shales and the Middle Cretaceous of very fossiliferous limestone. There is considerable difference of opinion as to the chronology of the succeeding beds, and the boundary between the Cretaceous and Tertiary systems is drawn at various horizons by different observers. The Cerro de Oro series is the most important group of these beds and takes a considerable share in the formation of the mountain ranges. It belongs either to the Upper Cretaceous or to the Lower Tertiary, or possibly in part to the one and in part to the other.[1] (P. La.)

Climate.—The climate of Venezuela is everywhere tropical except where modified by altitude. In the Maritime Andes at and above the altitude of Carácas it may be described as semi-tropical, and in the still higher regions of western Venezuela it approaches the mild temperate. On the coast and the northern slopes of the Maritime Andes the tropical heat is greatly modified by the trade-winds. At La Guaira the mean temperature for the year is 85° F., at Carácas (3025 ft.) it is 71·2° (or 66·2° according to an official return), at Cumaná it is 83°, at Valencia 76°, Coro 82°, Barquisimeto 78°, Yaritagua 80·6°, Mérida 61°, Trujillo 72°, and Maracaibo 81°. South of the sierras, however, the climate is much drier and hotter. The low temperatures of the night in these regions lower the mean annual temperatures. At Calabozo, for instance, the mean is about 88°, though the maximum in summer is not far from 100°. At Ciudad Bolívar, which is less sheltered from the trade-winds, the mean is 83° and the maximum 91·4°. The lowest temperatures recorded in official reports are those of Mucuchíes, in the state of Mérida, where the maximum is 68°, the minimum 43° and the mean 56°. The year is divided into two seasons, the dry and wet, the latter occurring from April to October, when the temperature is also the highest. On the *llanos* the dry season destroys the pasturage completely, dries up the small streams and lagoons, and compels many animals of semi-aquatic habits to aestivate. At Carácas the annual rainfall ranged from 602 to 863 millimetres between 1894 and 1902. In general the climate of Venezuela is healthy wherever the ocean winds have free access. Sheltered places in the lowlands, especially near streams and lagoons, are malarial and enervating, and at some points on the coast are subject to dangerous fevers. The sanitary condition is generally bad, and many forms of disease prevail that are not due to the climate.

Fauna.—The fauna and flora of Venezuela are similar in nearly all respects to those of the neighbouring regions of Guiana, Brazil and Colombia, the open *llanos* of the Orinoco being something of a neutral district between the great forested regions on the E., S. and W. Among the animals indigenous to the country are seven species of the cat family, including the puma, the jaguar and the ocelot; the wild dog (*Canis Azarae*); several representatives of the marten family, including two species of *Galictis*, two of the otter (*Lutra brasiliensis* and *L. pteronura*) and one of the skunk; two species of bear (*Ursus ornatus* and *U. nasutus*); and the "kinkajou." There are six species of monkey corresponding to those of Guiana and the Amazon valley, the sloth and ant-eater, 12 known genera of rodents, including many species of *Mures*, the cavy, the capybara, the paca, the nutria, the agouti, the tree porcupine, *Loncheres cristata*, *Echimys cayen* and the Brazilian hare. Among the pachyderms the tapir is found in the forests of the Orinoco. There are two species of the peccary, *Dicotyles torquatus* and *D. labiatus*. There are also 2 species of deer, *Cervus rufus* and *C. simplicornis*. There are 3 species of opossum. On the coast and in the Orinoco there may be found the manatee and the dolphin. The Reptilia include 11 species of the crocodile, alligator and lizard, including the savage *jacaré* of the Amazon, several species of turtle, 4 species of batrachians, and 29 species of serpents, including the striped rattlesnake (*Crotalus durissus*), *Lachesis mutus*, and a rather rare species of *Cophias*. Among the non-venomous species, the commonest are the boa-constrictor, the anaconda (*Eunectes murinus*) and the *Coluber variabilis*. Bird life is represented chiefly by migratory species, particularly of genera that inhabit the shores of streams and lagoons. The shallow lagoons of the *llanos*, like those of the Argentine *pampas*, are favourite fishing grounds for these birds. In the *garzeros* of Venezuela are to be found nearly every kind of heron, crane, stork and ibis, together with an incredible number of Grallatores. Ducks are also numerous in species and individuals, including a small bird called the *guiriri*, in imitation of its cry. Birds of prey are numerous. One species, the guacharo (*Steatornis caripensis*), or oil-bird, is commonly said to occur only in Venezuela, though it is found in Colombia and Ecuador also. They live in caves, especially in Caripe, and are caught in large numbers for the oil extracted from them, which is commonly known as "Caripe butter." The bell-bird (*Chasmorhynchus carunculatus*) is common in the forests of the Orinoco. Insect life is perhaps poorer and less varied than in Brazil, but in the 14 orders of insects there are no less than 98 families, each including many genera and species. There are 8 families of Coleoptera, 6 of Orthoptera, 23 of Hymenoptera, 14 of Lepidoptera and 7 of Diptera. Locusts are very numerous in the interior, and commit great ravages. Molluscs are common on the coasts, including the pearl oyster, and in the fresh-water streams and lakes. The coral polyp is also found in Venezuelan waters. The domestic animals

Karsten, *Géologie de la Colombie Bolivarienne* (Berlin, 1886); W. Sievers, "Karten zur physikalischen Geographie von Venezuela," *Peterm. Mittheil.* vol. xlii. (1896), pp. 125–29, pl. x.

of Venezuela—the horse, ass, ox, sheep, goat, hog, dog, cat, &c.—are not indigenous.

Flora.—The flora of Venezuela covers a wide range because of the vertical climatic zones. The coastal zone and lower slopes of all the mountains, including the lower Orinoco region and the Maracaibo basin, are clothed with a typical tropical vegetation. There is no seasonal interruption in vegetation. The tropical vegetation extends to an altitude of about 1300 ft., above which it may be classed as semi-tropical up to about 3500 ft., and temperate up to 7200 ft., above which the vegetation is Alpine. Palms grow everywhere; among them the coco-nut palm (*Cocos nucifera*) is the most prominent. There are some exotics in this zone, like the mango, which thrive so well that they are thought to be indigenous. The cacau is at its best in the humid forests of this region and is cultivated in the rich alluvial valleys, and the banana thrives everywhere, as well as the exotic orange and lemon. On the mountain slopes orchids are found in great profusion. Sugar-cane is cultivated in the alluvial valleys and coffee on their slopes up to a height of about 2000 ft. Among the many tropical fruits found here are bananas, guavas, mangoes, cashews, bread-fruit, aguacates, papayas, zapotes, granadillas, oranges, lemons and limes. In the next zone are grown many of the cereals (including rice), beans, tobacco, sugar-cane, peaches, apricots, quinces and strawberries. The *llanos* have some distinguishing characteristics. They are extensive grassy plains, the lowest being the bed of an ancient inland lake about which is a broad terrace (*mesa*), the talus perhaps of the ancient encircling highlands. The lower level has extensive lagoons and swampy areas and suffers less from the long periodical drought. Its wild grasses are luxuriant and a shrubby growth is found along many of its streams. The decline in stock-breeding resulted in a considerable growth of trees and chaparral over the greater part of the plain. A large part of the chaparral consists of the *chaparro*, a low evergreen oak of hardy characteristics, mixed with mimosa, desmauthus, zonia and others. Much of this region is covered with *gamelote*, a tall, worthless, grass with sharp stiff blades. One of the most remarkable palms of the Orinoco region is the "moriche" (*Mauritia flexuosa*). The fruit is edible and its juice is made into beer; the sap of the tree is made into wine, and its pith into bread; the leaves furnish an excellent thatch, and the fibre extracted from their midribs is used for fish lines, cordage, hammocks, nets, &c.; and the wood is hard and makes good building material. The fruit of the *Guilielma* is also widely used for food among the natives. Among other forest trees of economic importance are the silk-cotton tree (*Bombax ceiba*), the *palo de vaca*, or cow-tree (*Brosimum galactodendron*), whose sap resembles milk and is used for that purpose, the *Inga saman*, the *Hevea guayanensis*, celebrated in the production of rubber, and the *Attalea speciosa*, distinguished for the length of its leaves.

The principal economic plants of the country are cacau, coffee, cassava (manioc) called "mandioca" in Brazil, Indian corn, beans, sweet potatoes, taro, sugar-cane, cotton and tobacco. Of these coffee and sugar-cane were introduced by Europeans.

Population.—The population of Venezuela is largely a matter of conjecture, no census having been taken since the third general census of 1891, which gave a total population of 2,323,527, of which 1,137,139 were males and 1,186,388 females, and there were 42,898 foreign residents. The official *Handbook of Venezuela* for 1904 estimated the population for the preceding year as 2,663,671. The population consists of a small percentage of whites of European descent, chiefly Spaniards, various tribes and settlements of Indians, largely of the Arawak and Carib families, and a large percentage of *mestizos*, or mixed bloods. There is a large admixture of African blood. Hübner estimates the mixed of all races at 93%, the highest among all the South American nationalities, and the creoles at 1% only; but this is clearly incorrect. Perhaps a closer approximation would be to rate the creole element (whites of European descent) at 10%, as in Colombia, and the mixed races at 70%, the remainder consisting of Africans, Indians and resident foreigners.

Territorial Divisions.—The territorial divisions of Venezuela have been subjected to many changes. Under the constitution of the 27th of April 1904, the republic was divided into 13 states, 1 federal district and 5 territories, the names of which are as follows, those of the capital cities being given in brackets: Federal District (Carácas and La Asunción); Aragua (La Victoria); Bermúdez (Cumana); Bolívar (Ciudad Bolívar); Carabobo (Valencia); Falcón (Coro); Guárico (Calabozo); Lara (Barquisimeto); Mérida (Mérida); Miranda (Ocumare); Táchira (San Cristóbal); Trujillo (Trujillo); Zamora (San Carlós); Zulia (Maracaibo), with the following territories: Amazonas (San Fernando de Atabapo); Colón (Gran Roque); Cristobal Colón (Cristobal Colón); Delta-Amacuro (San José de Amacuro); Yaruari (Guacipati).

On the 5th of August 1909, however, a new division was promulgated, giving 20 states, 1 federal district and 2 territories. Under this division some of the recognized administrative units were greatly altered in area or even abolished, and the capital status of several cities was apparently affected. The division was as follows: Federal District (Carácas); Anzoátegui (Barcelona); Apuré (San Fernando de Apuré); Aragua (La Victoria); Bolívar (Ciudad Bolívar); Carabobo (Valencia); Cojedes (San Carlós); Falcón (Coro); Guárico (Calabozo); Lara (Barquisimeto); Mérida (Mérida); Miranda (Ocumare); Monagas (Maturín); Nueva Esparta (La Asunción); Portuguesa (Guanare); Sucre (Cumaná); Táchira (San Cristóbal); Trujillo (Trujillo); Yaracuy (San Felipe); Zamora (Barinas); Zulia (Maracaibo), with the following territories: Amazonas (San Fernando de Atabapo); Delta-Amacuro (Tucupita).

Communications and Commerce.—There has been no great development of railway construction in Venezuela, partly on account of political insecurity and partly because of the backward industrial state of the country. In 1908 there were only 13 railway lines with a mileage of about 540 m., including the short lines from Carácas to El Valle and La Guaira to Maiquetia and Macuto, and the La Vela and Coro. The longest of these is the German line from Carácas to Valencia (111 m.), and the next longest the Great Táchira, running from Encontrada on Lake Maracaibo inland to Uracá (71 m.), with a projected extension to San Cristóbal. Another line in the Lake Maracaibo region is known as the Great La Ceiba, and runs from a point near the lake to the vicinity of Valera and Trujillo. An important line connects the thriving city of Barquisimeto with the port of Tucacas. The best known of the Venezuelan railways is the short line from La Guaira to Carácas (22¾ m.), which scales the steep sides of the mountain behind La Guaira and reaches an elevation of 3135 ft. before arriving at Carácas. It is a British enterprise, and is one of the few railways in Venezuela that pay a dividend. The Puerto Cabello and Valencia line (34 m.) is another British undertaking and carries a good traffic. A part of this line is built with a central cog-rail. Probably a return to settled political and industrial conditions in Venezuela will result in a large addition to its railway mileage, as a means of bringing the fertile inland districts into direct communication with the coast.

In steamship lines the republic has almost nothing to show. A regular service is maintained on Lake Maracaibo, one on Lake Valencia, and another on the Orinoco, Apuré and Portuguesa rivers, starting from Ciudad Bolívar.

The coast of Venezuela has an aggregate length of 1876 m., and there are 32 ports, large and small, not including those of Lakes Maracaibo and Tacarigua and the Orinoco. The great majority of these have only a limited commerce, restricted to domestic exchanges. The first-class ports are La Guaira, Puerto Cabello, Ciudad Bolívar, Maracaibo and Carupano, and the second-class are Sucre, Juan Griego, Guiria, Caño Colorado, Guanta, Tucacas, La Vela and Porlamar. The commerce of these ports, both in the foreign and domestic trade, is small, tariff regulations being onerous, and the people too impoverished to be consumers of much beyond the barest necessaries of life. The total foreign trade in 1908 amounted to $9,778,810 imports and $14,560,830 exports, the values being in U.S. gold. The exports to the United States were valued at $5,550,073 and to France $5,496,627. The principal exports were coffee, cacau, divi-divi, rubber, hides and skins, cattle and asphalt. The imports include manufactured articles of all kinds, hardware and building materials, earthenware and glassware, furniture, drugs and medicines, wines, foodstuffs, coal, petroleum and many other things. The coasting trade is largely made up of products destined for exportation, or imports trans-shipped from the first-class ports to the smaller ones which have no direct relations with foreign countries. In the absence of statistical returns it is impossible to give the values of this branch of trade. The exchanges of domestic products are less important than they should be. The Orinoco trade is carried on almost wholly through Port of Spain, Trinidad, where merchandise and produce is transferred between light draught river boats and foreign ocean-going steamers. The distance from Port of Spain to Ciudad Bolívar is 299 m. and the traffic is carried by foreign-owned steamers. Under the administration of President Cipriano Castro this traffic was suspended for a long time, and trans-shipments were made at La Guaira. Above Ciudad Bolívar transportation is effected by two or three small river steamers and a great number of small craft (*lauchas, bungos, balandras*, &c.), using sails, oars and punting poles.

Agriculture.—The principal industries of Venezuela are agricultural and pastoral. Both have suffered heavily from military operations, but still they have remained the basis of Venezuelan wealth and progress. Much the greater part of the republic is fertile and adapted to cultivation. Irrigation, which has not been used to any great extent, is needed in some parts of the country for the best results, but in others, as in the valleys and on the northern slopes of the Maritime Andes, the rainfall is sufficiently well distributed to meet most requirements. The long dry season of the *llanos* and surrounding slopes, which have not as yet been devoted to cultivation, will require a different system of agriculture with systematic irrigation. In colonial times the *llanos* were covered with immense herds of cattle and horses and were inhabited by a race of hardy, expert horsemen, the *llaneros*. Both sides in the War of Independence drew upon these herds, and the *llaneros* were among the bravest in both armies. The end of the war found the *llanos* a desert, both herds and herdsmen having nearly disappeared. Successive civil wars prevented their recovery, and these great plains which ought to be one of the chief sources of meat supply for the world are comparatively destitute of stock, and the only source of revenue from this industry is the small number of animals shipped to the West Indies. The breeding of goats and swine is an important industry in some regions. The climatic conditions are not so favourable as in Argentina, but these are counterbalanced to some extent by the great river system of the Orinoco, whose large navigable tributaries cross the plains from end to end, and whose smaller streams from the surrounding highlands provide superior opportunities for water storage and irrigation. On the *mesas* alfalfa could be substituted for the native grasses and be used for stock when the pasturage of the lower plains is not available. Other industries of the colonial period were the cultivation of indigo and tobacco. The former has nearly disappeared, but the latter is still one of the more important products of the country. The best known tobacco-producing localities are Capadare, Yaritagua, Mérida, Cumanacoa, Guanape, Guaribe and Barinas. The best quality is that from the Capadare district, in the state of Falcón, which rivals that of the Vuelta Abajo of Cuba. No effort is made to improve the Venezuelan product, a part of which is exported to Cuba for cigar making. The principal agricultural products are coffee, cacau (cacao), sugar, Indian corn and beans. Coffee was introduced from Martinique in 1784 and its exportation began five years later. It is grown at elevations of 1600 to 3000 ft., and the yield is reported to be ¼ to ½ ℔ per tree, which is much less than the yield in São Paulo, Brazil. An official work (Veloz Goiticoa, *Venezuela*, Washington, 1904) gives the number of coffee trees in Venezuela as 250,000,000 belonging to 33,000 estates; the output was 42,806 tons in 1907. Several grades are produced in Venezuela, determined by geographical position, altitude and method of curing and preparing for market. The Maracaibo type from the mountain-slopes of Mérida, Trujillo and Táchira is perhaps the best known and brings the best price. Cacau (*Theobroma cacao*) is an indigenous product and is extensively cultivated on the Caribbean slopes. It requires a high temperature (about 80° F.), rich soil and a high degree of humidity for the best development of the tree. The tree has an average height of 12–13 ft., begins bearing five years after planting, requires little attention beyond occasional irrigation, bears two crops a year (June and December), and produces well until it is forty years of age—the yield being from 490 to 600 ℔ per acre of 100 trees. There are two grades of Venezuelan cacau—the *criollo* or native, and the *trinitario*, or Trinidad, the first being superior in quality. The best cacau comes from the vicinity of Carácas and is marketed under that name. The exportation of 1907 was about 14,000 tons. Sugar-cane is not indigenous, but it is cultivated with marked success in the lowlands ol Zulia, and at various points on the coast. The industry, however, has not kept pace with its development in other countries and, in great part, still employs antiquated methods and machinery. Its principal product is "papelón," or brown sugar, which is put on the market in the shape of small cylindrical and cubical masses of 1¾ to 3½ ℔ weight. This quality is the only one consumed in the country, with the exception of a comparatively small quantity of granulated, and of refined sugar in tablets prepared for people of the well-to-do classes. The annual output is about 3000 tons. Cotton was produced in several places in colonial times, but the output has declined to a few thousand pounds. The plant is indigenous and grows well, but, unlike cacau, it requires much manual labour in its cultivation and picking and does not seem to be favoured by the planters. Indian corn is widely grown and provides the staple food of the people, especially in the interior. Beans also are a common food, and are universally produced, especially the black bean. Wheat was introduced by the Spaniards immediately after their occupation of Venezuela, and is grown in the elevated districts of Aragua and the western states, but the production does not exceed home consumption. Rice is a common article of food and is one of the principal imports. Several states are offering bounties to encourage its cultivation at home. Other agricultural products are sweet potatoes, cassava (manioc), yuca, yams, white potatoes, maguey, okra, peanuts, pease, all the vegetables of the hot and temperate climates, oranges, lemons, limes, bananas, plantains, figs, grapes, coco-nuts, pine-apples, strawberries, plums, guavas, breadfruit, mangoes and many others. There are also many fruits found growing wild, like those of the cactus and various palms, and these are largely consumed. The forest products, whose collection and preparation form regular industries, are rubber (called *caucho* or *goma*), tonka beans, vanilla, copaiba, chique-chique, sarsaparilla, divi-divi, dye-woods, cabinet-woods and fibres. The rubber forests are on the Orinoco and its tributaries of the Guiana highlands.

Mining.—The principal minerals are gold, copper, iron, sulphur, coal, asphalt and petroleum. Silver, tin, lead, mercury and precious stones are listed among the mineral resources of the country, but no mines have been developed, and they are possibilities only. Gold is found throughout a wide area, but chiefly in the Yuruari region, about 100 m. S.W. of the principal mouth of the Orinoco and near the borders of British Guiana, where the famous El Callao mines are. These mines have produced as much as 181,040·2 Spanish oz. in one year (1886) and a total of 1,320,929·09 oz. from 1871 to 1890, while another report gives an output valued at $23,000,000 U.S. gold in the fifteen years from 1884 to 1899. The production since then has greatly declined. There are 14 copper mines in the country, those at Aroa, 70 m. W. of Puerto Cabello and in railway communication with Tucacas (89 m.), being the most productive. They date from 1605 and now belong to an English company. The output from 1878 to 1891 was 329,218 tons of ore and 53,053 tons of regulus, valued at £2,794,986. Iron of a good quality has been found in the Imataca region, Delta-Amacuro territory, 53 m. from the "Boca Grande" of the Orinoco. The principal coal deposits developed are at Naricual, near Barcelona, and a railway has been constructed to bring the output to the port of Guanta. Asphalt is taken from several deposits—from Maracaibo, Cumaná and Pedernales in the Orinoco delta. The latter place also yields petroleum. Sulphur is mined near Carúpano, and salt in Zulia and on the peninsula of Araya. The latter is a government monopoly, and the high prices at which it is sold constitute a serious prejudice to the people and to industries like that of meat packing.

Pearl Fisheries.—One of the oldest of Venezuelan industries, the Margarita pearl fisheries, was prohibited in 1909 for an indefinite time because of the threatened extinction of the oyster beds. The industry dates from the first exploration of this coast and was probably carried on before that by the natives. The fisheries are established about the islands of Margarita, Coche and Cubagua, the best producing beds being at El Tirano and Macanao, the first N.E. and the other N.W. of Margarita. The natives engaged in the fishery used some 400 sailboats of 3 to 15 tons capacity, and the beds were raked in search of pearl oysters. In 1900 a concession was granted for an exclusive right to fish for pearls, &c., between Margarita and the coast, the contractor to use submarine apparatus.

Manufactures.—There are few manufacturing industries in Venezuela, and these usually of the parasitic type, created by official favour and protected by high tariffs on imports in competition. The manufactures of this class include aerated waters, beer, candles, chocolate, cigarettes, cotton fabrics, hats, ice, matches, boots and shoes, drugs and medicines. There are a number of electric plants, three of which use water power, one at El Encantado, 10 m. from Carácas, one at Mérida, and the third at San Cristóbal, Táchira. The plants using steam for motive power are at Carácas, Maracaibo, Valencia and Puerto Cabello. There has been some development in the manufacture of agricultural machinery and implements, vehicles, pianos and furniture, and some older industries, such as tanning leather and the manufacture of saddles and harness, the milling of wheat and Indian corn, distilling, soap-making, &c. At Guanta there is a factory for the manufacture of patent fuel from Naricual coal and asphalt. In 1901 there was one *saladero*, or meat-packing establishment, in the Orinoco-Apuré region, but it did not prove successful because of the high cost of salt.

Government.—The government of Venezuela is that of a federal republic of nominally independent, self-governing states, administered according to the provisions of the constitution of the 27th of April 1904, modified or revised on the 5th of August 1909. The legislative power is nominally vested in a national Congress of two houses—the Senate and Chamber of Deputies—which meets at Carácas every two years on the 23rd of May, the session lasting 90 days. The Senate consists of two members from each state, or 40 members, who are elected by the state legislatures for a period of four years. A senator must be a native-born citizen and not less than thirty years of age. The Chamber consists of popular representatives, elected by direct vote, in the proportion of one deputy for each 35,000 of population, each state being entitled to at least one deputy, or two in case its population exceeds 15,000, the federal district and territories being entitled to representatives on the same terms. A deputy must also be a native-born citizen, not less than twenty-one years of age, and is elected for a period of four years.

The executive power is vested by the constitution in a president, two vice-presidents and a cabinet of ministers. The president and vice-presidents, who must be Venezuelans by birth and more than thirty years old, are elected by an electoral body or council composed of members of the national Congress, one member from each state and the Federal District. This council elects by an absolute majority of votes. The presidential term is four years (it was six years under the constitution of 1904), and the president cannot succeed himself. The powers of the executive, direct and implied, are very broad and permit the exercise of much absolute authority. The president is assisted by a cabinet of seven ministers and the governor of the federal district, their respective departments being interior, foreign relations, finance and public credit, war and marine, *fomento* (promotion), public works and public instruction. The ministers are required to countersign all acts relating to their respective departments, and are held responsible both before Congress and the courts for their acts. The department of *fomento* is charged with the supervision of all matters relating to agriculture, stock-raising, mines, industries, commerce, statistics, immigration, public lands, posts, telegraphs and telephones. The department of the interior is also charged with matters relating to the administration of justice, religion and public worship.

The judicial power is vested in a supreme federal court, called the Corte Federal y de Casación, and such subordinate tribunals as may be created by law. As the laws and procedure are uniform throughout the republic and all decrees and findings have legal effect everywhere, the state judicial organizations may be considered as taking the place of district federal courts, although the constitution does not declare them so. The federal court consists of 7 members, representing as many judicial districts of the republic, who are elected by Congress for periods of six years (Const. 1904), and are eligible for re-election. It is the supreme tribunal of the republic, having original jurisdiction in cases of impeachment, the constitutionality of laws, and controversies between states or officials. It is also a court of appeal (*Casación*) in certain cases, as defined by law. The judicial organization of the states includes in each a supreme court of three members, a superior court, courts of first instance, district courts and municipal courts. The judicial terms in the states are for three years. In the territories there are civil and criminal courts of first instance, and municipal courts. The laws of Venezuela are well codified both as to law and procedure, in civil, criminal and commercial cases.

The state governments are autonomous and consist of legislative assemblies composed of deputies elected by ballot for a period of three years (Const. 1904), which meet in their respective state capitals on the 1st of December for sessions of thirty days, and for each a president and two vice-presidents chosen by the legislative assembly for a term of three years. The states are divided into districts and these into *municipios*, the executive head of which is a *jefe politico*. There is a municipal council of seven members in each district, elected by the municipios, and in each municipio a communal junta appointed by the municipal council. The governors of the federal territories are appointees of the president of the republic, and the *jefe politico* of each territorial municipio is an appointee of the governor. The Federal District is the seat of federal authority, and consists of a small territory surrounding Carácas and La Guaira, known in the territorial division of 1904 as the West district, and the island of Margarita and some neighbouring islands, known as the East district.

There are two classes of citizens in Venezuela—native-born and naturalized. The first includes the children of Venezuelan parents born in foreign countries; the latter comprises four classes: natives of Spanish-American republics, foreign-born persons, foreigners naturalized through special laws and foreign women married to Venezuelans. The power of granting citizenship to foreigners is vested in the president of the republic, who is also empowered to refuse admission to the country to undesirable foreigners, or to expel those who have violated the special law (April 11, 1903) relating to their conduct in Venezuelan territory. The right of suffrage is exercised by Venezuelan males over 21 years of age, and all electors are eligible to public office except where the constitution declares otherwise. Foreign companies are permitted to transact business in Venezuela, subject to the laws relating to non-residents and also to the laws of the country governing national companies.

Army.—The military forces of Venezuela consist nominally of about 20 battalions of infantry, of 400 men each, and 8 batteries of artillery, of 200 men each. There is also a battalion of marines employed about the ports and in the arsenals. The organization and equipment is defective, and the force deficient in numbers and discipline. The police force and fire companies in the larger cities are organized on a military basis, and are sometimes used for military purposes. For a people so accustomed to revolutionary outbreaks, the Venezuelans are singularly deficient in military organization. There is no lack of officers of the highest grades, but the rank and file are not uniformed, equipped or drilled, and military campaigns are usually irregular in character and of comparatively short duration. It should be said that Venezuela has a modern military organization so far as law can make it. It is drawn in imitation of European models, and makes military service compulsory for all Venezuelans between 21 and 50 years. This national force is divided into actives and reserves, the strength of the first being fixed by Congress, and all the rest, of unknown number, belong to the latter. The provisions of the law, however, have never been enforced, and the actives or regular army are recruited by impressment rather than through conscription. There is a military academy at Carácas, and battalion schools are provided for officers and privates, but they are of little value.

Education.—In popular education Venezuela has done almost nothing worthy of record. As in Chile, Peru and Colombia, the ruling classes and the Church have taken little interest in the education of the Indians and *mestizos*. Venezuela, it is true, has a comprehensive public instruction law, and attendance at the public schools is both gratuitous and nominally compulsory. But outside the cities, towns and large villages near the coast there are no schools and no teachers, nor has the government done anything to provide them. This law has been in force since about 1870, but on the 30th of June 1908 there were only 1150 public schools in the republic with a total enrolment of 35,777 pupils. There are a number of parochial and conventual schools, the church being hostile to the public-school system. An overwhelming majority of the people is illiterate and is practically unconscious of the defect. In 1908 the educational facilities provided by the republic, not including some private subventioned schools, were two universities and thirty-three national colleges. The universities are at Carácas and Mérida, the latter known as the Universidad de los Andes. The Carácas institution dates from early colonial times and numbers many prominent Venezuelans among its alumni. The national college corresponds to the lyceum and high school of other countries. There are law, medical and engineering schools in the country, but one rarely hears of them. The episcopal seminaries are usually good, especially the one at Carácas. In addition to these, there are normal, polytechnic, mining and agricultural schools, the last at Carácas and provided with a good library and museum. There are several mechanics' schools (*Artes y Oficios*) in the larger cities, and a large number of private schools. Further educational facilities are provided by a national library with about 50,000 volumes, a national museum, with a valuable historical collection, the Cajigal Observatory, devoted to astronomical and meteorological work, and the Venezuelan Academy and National Academy of History—the first devoted to the national language and literature, and the second to its history.

Religion.—The Roman Catholic is the religion of the state, but freedom of worship is nominally guaranteed by law. The president, however, is empowered to deny admission into the country of foreigners engaged in special religious work not meeting his approval. Practically no other form of worship exists in the country than that of the Roman Catholic Church, the Protestant and other denominations holding their services in inconspicuous chapels or private apartments in the larger cities, where considerable numbers of foreigners reside. The state contributes to the support of the Church, builds its churches and provides for the salaries of its clergy, and at the same time it has the right to approve or reject all ecclesiastical appointments and to permit or forbid the execution of all decrees of the Roman See relating to Venezuela. The Church hierarchy consists of one archbishop (Carácas) and four suffragan bishops (Mérida, Guáyana, Barquisimeto and Guárico).

Finance.—The financial situation in Venezuela was for a long time extremely complicated and discreditable, owing to defaults in the payment of public debts, complications arising from the guarantee of interest on railways and other public works, responsibility for damages to private property during civil wars and bad administration. To meet increasing obligations, taxation has been extended and heavily increased. The public revenues are derived from customs taxes and charges on imports and exports, transit taxes, cattle taxes, profits on coinage, receipts from state monopolies, receipts from various public services such as the post office, telegraph, Carácas waterworks, &c., and sundry taxes, fines and other sources. From 60 to 70% of the revenue is derived from the custom-house, and the next largest source is the transit tax. The official budget returns for 1904–6 show the revenues and expenditures to have been—

	1904. *Bolívares.*	1905. *Bolívares.*	1906. *Bolívares.*
Revenue . . .	57,576,741	49,385,379	49,293,067
Expenditure . . .	52,925,521	54,718,163	51,874,694

A considerable part of the expenditure since 1903 consists of payments on account of foreign debts which Venezuela was compelled to satisfy. To meet these, taxes were increased wherever possible, thus increasing both sides of the budget beyond its normal for those years.

The public debt of Venezuela dates back to the War of Independence, when loans were raised in Europe for account of the united colonies of Colombia, Ecuador and Venezuela. The separation of the Colombian republic into its three original parts took place in 1830, and in 1834 the foreign debt contracted was divided among the three, Venezuela being charged with 28½%, or £2,794,826, of which £906,430 were arrears of interest. Other items were afterwards added to liquidate other obligations than those included in the above, chiefly on account of the internal debt. Several conversions and compositions followed, interest being paid irregularly. In 1880–81 there was a consolidation and conversion of the republic's foreign indebtedness through a new loan of £2,750,000 at 3%, and in 1896 a new loan of 50,000,000 *bolívares* (£1,980,198) for railway guarantees and other domestic obligations. In August 1904 these loans and arrears of interest brought the foreign debt up to £5,618,725, which in 1905 was converted into a "diplomatic" debt of £5,229,700 (3%). During these years Venezuela had been pursuing the dangerous policy of granting interest guarantees on the construction of railways by foreign corporations, which not only brought the government into conflict with them on account of defaulted payments, but also through disputed interpretations of contracts and alleged arbitrary acts on the part of government officials. In the civil wars the government was also held responsible for damages to these properties and for the mistreatment of foreigners residing in the country. Some of these claims brought Venezuela into conflict with the governments of Great Britain, Germany and Italy in 1903, and Venezuelan ports were blockaded and there was an enforced settlement of the claims (about £104,417), which were to be paid from 30% of the revenues of the La Guaira and Puerto Cabello custom-houses. This settlement was followed by an adjustment of all other claims, payment to be effected through the same channels. In 1908 (July 31) the total debt of Venezuela (according to official returns) consisted of the following items:—

	Bolívares.
Consolidated internal debt	63,171,818
Diplomatic debt (Spanish, French and Dutch) .	7,014,569
„ „ (French, 1903–4)	5,733,490
„ „ of 1905	132,049,925
Unconsolidated debt in circulation	4,561,742
Total .	212,531,544
or, at 25¼ *bolívares* per £,	£8,417,091

The currency of Venezuela is on a gold basis, the coinage of silver and nickel is restricted, and the state issues no paper notes. Foreign coins were formerly legal tender in the republic, but this has been changed by the exclusion of foreign silver coins and the acceptance of foreign gold coins as a commodity at a fixed value. Under the currency law of the 31st of March 1879, the thousandth part of a kilogramme of gold was made the monetary unit and was called a *bolívar*, in honour of the Venezuelan liberator. The denominations provided for by this law are—

Gold: 100, 50, 20, 10 and 5 *bolívares*.
Silver: 5, 2, 1 *bolívares*; 50, 20 *céntimos*.
Nickel: 12½ and 5 *céntimos*.

These denominations are still in use except the silver 20-*céntimos* piece, which was replaced by one of 25 *céntimos* in 1891. The silver 5-*bolívar* piece is usually known as a "dollar," and is equivalent to 48¼ pence, or 96½ cents U.S. gold. The old "peso" is no longer used except in accounts, and is reckoned at 4 *bolívares*, being sometimes described as a "soft" dollar. Silver and nickel are legal tender for 50 and 20 *bolívares* respectively. Paper currency is issued by the banks of Venezuela, Carácas and Maracaibo under the provisions of a general banking law, and their notes, although not legal tender, are everywhere accepted at their face value.

The metric weights and measures have been officially adopted by Venezuela, but the old Spanish units are still popularly used throughout the country. (A. J. L.)

History.—The coast of Venezuela was the first part of the American mainland sighted by Columbus, who, during his third voyage in 1498, entered the Gulf of Paria and sailed along the coast of the delta of the Orinoco. In the following year a much greater extent of coast was traced out by Alonzo de Ojeda, who was accompanied by the more celebrated Amerigo Vespucci. In 1550 the territory was erected into the captain-generalcy of Carácas, and it remained under Spanish rule till the early part of the 19th century. During this period negro slaves were introduced; but less attention was given by the Spaniards to this region than to other parts of Spanish America, which were known to be rich in the precious metals.

In 1810 Venezuela rose against the Spanish yoke, and on the 14th of July 1811 the independence of the territory was proclaimed. A war ensued which lasted for upwards of ten years and the principal events of which are described under Bolivar (*q.v.*), a native of Carácas and the leading spirit of the revolt. It was not till the 30th of March 1845 that the independence of the republic was recognized by Spain in the treaty of Madrid. Shortly after the battle of Carabobo (June 24, 1821), by which the power of Spain in this part of the world was broken, Venezuela was united with the federal state of Colombia, which embraced the present Colombia and Ecuador; but the Venezuelans were averse to the Confederation, and an agitation was set on foot in the autumn of 1829 which resulted in the issue of a decree (December 8) by General Paez dissolving the union, and declaring Venezuela a sovereign and independent state. The following years were marked by recurring attempts at revolution, but on the whole Venezuela during the period 1830–1846 was less disturbed than the neighbouring republic owing to the dominating influence of General Paez, who during the whole of that time exercised practically dictatorial power. In 1849 a successful revolution broke out and Paez was driven out of the country. The author of his expulsion, General José Tadeo Monagas, had in 1847 been nominated, like so many of his predecessors, to the presidency by Paez, but he was able to win the support of the army and assert his independence of his patron. Paez raised the standard of revolt, but Monagas was completely victorious. For ten years, amidst continual civil war, Monagas was supreme. The chief political incident of his rule was a decree abolishing slavery in 1854. General Juan José Falcon, after some years of civil war and confusion, maintained himself at the head of affairs from 1863 to 1868. In 1864 he divided Venezuela into twenty states and formed them into a Federal republic. The twenty parties whose struggles had caused so much strife and bloodshed were the Unionists, who desired a centralized government, and the Federalists, who preferred a federation of semi-autonomous provinces. The latter now triumphed. A revolt headed by Monagas broke out in 1868, and Falcon had to fly the country. In the following year Antonio Guzman Blanco succeeded in making himself dictator, after a long series of battles in which he was victorious over the Unionists.

For two decades after the close of these revolutionary troubles in 1870 the supreme power in Venezuela was, for all practical purposes, in the hands of Guzman Blanco. He evaded the clause in the constitution prohibiting the election of a president for successive terms of office by invariably arranging for the nomination of some adherent of his own as chief of the executive, and then pulling the strings behind this figurehead. The tenure of the presidential office was for two years, and at every alternate election Guzman Blanco was declared to be duly and legally chosen to fill the post of chief magistrate of the republic. In 1889 there was an open revolt against the dictatorial system so long in vogue; and President Rojas Paul, Blanco's *locum tenens*, was forced to flee the country and take refuge in the Dutch colony of Curaçoa. A scene of riot and disorder was enacted in the Venezuelan capital. Statues of Blanco, which had been erected in various places in the city of Carácas, were broken by the mob, and wherever a portrait of the dictator was found it was torn to pieces. No follower of the Blanco regime was safe. An election was held and General Andueza Palacios was nominated president. A movement was set on foot for the reform of the constitution, the principal objects of this agitation being to prolong the presidential term to four years, to give Congress the right to choose the president of the republic, and to amend certain sections concerning the rights of persons taking part in armed insurrection arising out of political issues. All might have gone well for President Palacios had he not supposed that this extension of the presidential period might be made to apply to himself.

His attempt to force this question produced violent opposition in 1891, and ended in a rising headed by General Joaquin Crespo. This revolt, which was accompanied by severe fighting, ended in 1892 in the triumph of the insurgents, Palacios and his followers being forced to leave the country to save their lives. General Crespo became all-powerful; but he did not immediately accept the position of president. The reform of the constitution was agreed to, and in 1894 General Crespo was duly declared elected to the presidency by Congress for a period of four years. One of the clauses of the reformed constitution accords belligerent rights to all persons taking up arms against the state authority, provided they can show that their action is the outcome of political motives. Another clause protects the property of rebels against confiscation. Indeed, a premium on armed insurrection is virtually granted.

In April 1895 the long-standing dispute as to the boundary between British Guiana and Venezuela was brought to a crisis by the action of the Venezuelan authorities in arresting Inspectors Barnes and Baker, of the British Guiana police, with a few of their subordinates, on the Cuyuni river, the charge being that they were illegally exercising the functions of British officials in Venezuelan territory. Messrs Barnes and Baker were subsequently released, and in due course made their report on the occurrence. For the moment nothing more was heard of this boundary question by the public, but General Crespo instructed the Venezuelan minister in Washington to ask for the assistance of the United States in the event of any demand being made by the British Government for an indemnity. Whilst this frontier difficulty was still simmering, an insurrection against General Crespo was fomented by Dr J. P. Rojas Paul, the representative of the Blanco regime, and came to a head in October 1895, risings occurring in the northern and southern sections of the republic. Some desultory fighting took place for three or four months, but the revolt was never popular, and was completely suppressed early in 1896. The Guiana boundary question began now to assume an acute stage, the Venezuelan minister in Washington having persuaded President Cleveland to take up the cause of Venezuela in vindication of the principles of the Monroe doctrine. On the 18th of December 1895 a message was sent to the United States Congress by President Cleveland practically stating that any attempt on the part of the British Government to enforce its claims upon Venezuela as regards the boundary between that country and Guiana without resort to arbitration would be considered as a *casus belli* by his government. The news of this message caused violent agitation in Carácas and other towns. A league was formed binding merchants not to deal in goods of British origin; patriotic associations were established for the purpose of defending Venezuela against British aggression, and the militia were embodied. The question was subsequently arranged in 1899 by arbitration, and by the payment of a moderate indemnity to the British officers and men who had been captured. Diplomatic relations between the two countries, which had been broken off in consequence of the dispute, were resumed in 1897.

In 1898 General Crespo was succeeded as president by Señor Andrade, who had represented Venezuela in Washington during the most acute stage of the frontier question. Towards the end of the year a revolutionary movement took place with the object of ousting Andrade from power. The insurrection was crushed, but in one of the final skirmishes a chance bullet struck General Crespo, who was in command of the government troops, and he died from the effects of the wound. A subsequent revolt overthrew President Andrade in 1900. General Cipriano Castro then became president. During 1901 and 1902 the internal condition of the country remained disturbed, and fighting went on continually between the government troops and the revolutionists.

The inhabitants of Venezuela have a right to vote for the members of Congress, but in reality this privilege is not exercised by them. Official nominees are as a rule returned without any opposition, the details of the voting having been previously arranged by the local authorities in conformity with instructions from headquarters. In these circumstances the administration of public affairs fell into the hands of an oligarchy, who governed the country to suit their own convenience. President Castro was for eight years a dictator, ruling by corrupt and revolutionary methods, and in defiance of obligations to the foreign creditors of the country. The wrongs inflicted by him on companies and individuals of various nationalities, who had invested capital in industrial enterprises in Venezuela, led to a blockade of the Venezuelan ports in 1903 by English, German and Italian warships. Finding that diplomacy was of no avail to obtain the reparation from Castro that was demanded by their subjects, the three powers unwillingly had recourse to coercion. The president, however, sheltered himself behind the Monroe doctrine and appealed to the government of the United States to intervene. The dispute was finally referred by mutual consent to the Hague Court of Arbitration. The Washington government had indeed no cause to be well disposed to Castro, for he treated the interests of Americans in Venezuela with the same high-handed contempt for honesty and justice as those of Europeans. The demand of the United States for a revision of what is known as the Olcott Award in connexion with the Orinoco Steamship Company was in 1905 met by a refusal to reopen the case. Meanwhile the country, which up to the blockade of 1903 had been seething with revolutions, now became much quieter. In 1906, the president refused to allow M. Taigny, the French minister, to land, on the ground that he had broken the quarantine regulations. In consequence, France broke off diplomatic relations. In the following year, by the decision of the Hague Tribunal, the Venezuela government had to pay the British, German and Italian claims, amounting to £691,160; but there was still £840,000 due to other nationalities, which remained to be settled. The year 1907 was marked by the repudiation of the debt to Belgium, and fresh difficulties with the United States. Finally, in 1908 a dispute arose with Holland on the ground of the harbouring of refugees in Curaçoa. The Dutch Minister was expelled, and Holland replied by the despatch of gunboats, who destroyed the Venezuelan fleet and blockaded the ports. In December General Castro left upon a visit to Europe, nominally for a surgical operation. In his absence a rising against the dictator took place at Carácas, and his adherents were seized and imprisoned. Juan Vincenti Gomez, the vice-president, now placed himself at the head of affairs and formed an administration. He was installed as president in June 1910.

VENGURLA, a seaport on the west coast of India in Ratnagiri district, Bombay. Pop. (1901) 19,018. It was an early site of both Dutch and English factories, and was formerly the port for communication with the garrisons in the Southern Mahratta country. In the neighbourhood are the "Burnt Islands," with the Vengurla Rock lighthouse.

VENICE (*Venezia*), a city and seaport of Italy, occupying one of the most remarkable sites in the world. At the head of the Adriatic, between the mountains and the sea, lies that part of the Lombard plain known as the Veneto. The whole of this plain has been formed by the *débris* swept down from the Alps by the rivers Po, Ticino, Oglio, Adda, Mincio, Adige, Brenta, Piave, Livenza, Tagliamento and Isonzo. The substratum of the plain is a bed of boulders, covered during the lapse of ages by a deposit of rich alluvial soil. The rivers when they debouch from the mountains assume an eastern trend in their effort to reach the sea. The result is that the plain is being gradually extended in an easterly direction, and cities like Ravenna, Adria and Aquileia, which were once seaports, lie now many miles inland. The encroachment of land on sea has been calculated at the rate of about three miles in a thousand years. A strong current sets round the head of the Adriatic from east to west. This current catches the silt brought down by the rivers and projects it in long banks, or *lidi*, parallel with the shore. In process of time some of these banks, as in the case of Venice, raised themselves above the level of the water and became the true shore-line, while behind them lay large surfaces of water, called lagoons, formed partly by the fresh water brought down by the rivers, partly by the salt-water tide which found its way in by the channels of the river mouths. Along the coast-line, roughly speaking between the Apennines at Rimini and the Carnic Alps at Trieste, three main systems of lagoons were thus created, the lagoon of Grado or Marano to the east, the lagoon of Venice in the middle, and the lagoon of Comacchio to the south-west (for plan, see HARBOUR). All three are dotted with small islands, possibly the remains of some earlier *lido*. These islands are little else than low mud banks, barely rising above the water-level. On a group of these mud banks about the middle of the lagoon of Venice stands the city of Venice. It would be difficult to imagine a site less adapted for the foundation and growth of a great community. The soil is an oozy mud which can only be made capable of carrying buildings by the artificial means of pile-driving; there is no land fit for agriculture or the rearing of cattle; the sole food supply is fish from the lagoon, and there is no drinking-water save such as could be stored from the rainfall. Yet the group of islands called Rialto, in mid-Venetian lagoon, were first the asylum and then the magnificent and permanent home of a race that took a prominent part in the medieval and Renaissance history of Europe. The local drawbacks and difficulties once surmounted, Venice by her geographical position became the seaport nearest the heart of Europe.

Ethnography and Early History.—As to the ethnography of the race little is known that is certain. It has frequently been said that the lagoon population was originally composed of refugees from the mainland seeking asylum from the incursions of Huns, Goths and Lombards; but it is more probable that, long before the date of the earliest barbarian inroad, the lagoon islands already had a population of fisherfolk. In any case we may take it that the lagoon-dwellers were racially identical with the inhabitants of the neighbouring mainland, the Heneti or Veneti. That the Heneti themselves were immigrants is generally admitted. The earlier ethnographers, like Strabo, put forward three theories as to the original home of the race. Strabo himself talks of Armoric Heneti, and supposes them to have come from the neighbourhood of Brittany; another theory gives us Sarmatian Heneti, from the Baltic provinces; while the most widely accepted view was that they reached Italy from Paphlagonia. Modern scholarship has rejected these theories. Pauli and Kretschmer, proceeding on the basis of language, have reached conclusions which in the main are identical. Pauli, who has published all the known inscriptions of the Heneti, holds that the language is Illyrian, closely connected with Messapian. Kretschmer goes further and divides the Illyrian language into two sharply defined dialects, the northern dialect being represented by the Heneti. The result is that in the present condition of our knowledge we must conclude that the Heneti were a branch of the Illyrian people. The Eneti of Paphlagonia, the Veneti of Brittany and the Venedi of the Baltic, are probably quite distinct, and the similarity of name is merely a coincidence.

The dwellings of the primitive settlers in the lagoons were, in all probability, rude huts made of long reeds, such as may be seen to this day in the lagoon of Grado. A ditch was cut deep into the mud so as to retain the water at low tide, and there the boats of the fishermen lay. The ground about the hut was made solid and protected from corrosion by a palisade of wattled osiers, thus creating the earliest form of the *fondamenta*, or quay, which runs along the side of so many Venetian canals and is so prominent a feature in the construction of the city. Gradually, as time went on, and probably with the influx of refugees from the mainland, bricks made of lagoon mud came to take the place of wattle and reeds in the construction of the houses. Groups of dwellings, such as are still to be seen on some of the small canals at Burano, clustered together along the banks of the deeper channels which traverse the lagoon islands and give access to the tide. It is these channels which determined the lines of construction; the dwellings followed their windings, and that accounts for the extraordinarily complex network of calles and canals which characterizes modern Venice. The alleys or *calli* number 2327, with a total length of 89¾ m.; the canals number 177 and measure 28 m. The whole site of Venice is dominated by the existence of one great main canal, the Grand Canal, which, winding through the town in the shape of the letter S, divides it into two equal parts. This great canal was probably at one time the bed of a river flowing into the lagoons near Mestre. The smaller canals all serve as arteries to the Grand Canal. One other broad canal, once the bed of the Brenta, divides the island of the Giudecca from the rest of the city and takes its name from that island. The ordinary Venetian house was built round a courtyard, and was one storey high; on the roof was an open *loggia* for drying clothes; in front, between the house and the water, ran the *fondamenta*. The earliest churches were built with cemeteries for the dead; and thus we find the nucleus of the city of Venice, little isolated groups of dwellings each on its separate islet, scattered, as Cassiodorus[1] says, like sea-birds' nests over the face of the waters. Some of the islets were still uninhabited, covered with a dense low growth which served as cover for game and even for wolves.

With the destruction of the mainland cities by repeated barbarian invasions, and thanks to the gradual development of Venice as a centre of coasting trade in the northern Adriatic, the aspect of the city changed. Brick and more rarely stone took the place of wood and wattle. The assaults of the Dalmatian pirates, attracted by the growing wealth of the city, necessitated the building of strong castellated houses, of which no example has come down to our day, but we may gather what they were like from Petrarch's description of his house on the Riva degli Schiavoni, with its two flanking towers, probably retaining the primitive form, and also from the representations of protecting towers which occur in Carpaccio's pictures. The canals too were guarded by chains stretched across their mouths and by towers in some cases, as, for example, in the case of the Torresella Canal, which takes its name from these defence works. These houses clustered round the churches which now began to be built in considerable numbers, and formed the various *contrade* of the city. The *Cronica altinate* in the vision of Fra Mauro gives us a picturesque account of the founding of the various parishes, Olivolo or Castello, St Raffaello, St Salvadore, Sta Maria Formosa, S. Giovanni in Bragora, the Apostoli and Sta Giustina. Tradition has it that the earliest church in Venice was S. Giacomo di Rialto,

[1] Secretary to Theodoric the Great, in a letter dated A.D. 523.

said to have been founded in 432. The canals between these clusters of houses were deepened and cleared out, and in some cases trees were planted along the banks, or *fondamenta*; we hear of the cypresses on San Giorgio Maggiore, of an ancient mulberry tree at San Salvadore, of a great elder tree near the Procuratie Vecchie where the magistrates were wont to tie their horses. There were vineyards and orchards (*broli*) on land reclaimed from the sea, and lying between the various clusters of houses, which had not yet been consolidated into one continuous city. The canals were crossed by wooden bridges without steps, and in the case of the wide Grand Canal the bridge at Rialto was carried on boats. Gradually, however, stone bridges came into use. The earliest of these was the bridge of San Zaccaria, mentioned in a document of 1170. The Rialto bridge was designed in 1178 by Nicolo Barattieri, and was carried on pontoons. In 1255 and 1264 it was rebuilt, still in wood. It was carried on beams and could be raised in the middle, as we see it in Carpaccio's picture of "The Miracle of the Cross." The present bridge, the work of Antonio or Giovanni Contino, whose nickname was da Ponte, dates from 1588–91, and cost 250,000 ducats. The same architect was responsible for the lofty "Bridge of Sighs" (1595-1605), connecting the ducal palace with the state prisons (1591–97) on the opposite side of the narrow canal on the east of the Rio del Palazzo.

The early bridges were inclined planes and could easily be crossed by horses. It was not till the city became more populous and when stone-stepped bridges were introduced that the use of horses died out. As late as 1365 the Doge Lorenzo Celsi owned a famous stud of chargers, and in 1490 the Doge Michele Steno's stables, where the present Zecca stands, were famous throughout Italy. In 1392 a law put an end to riding in the Merceria, on account of the crowd, and all horses and mules were obliged to carry bells to warn foot-passengers. The lanes and alleys of the early city were unpaved and filthy with slops from the houses. But in the 13th century the Venetians began to pave the more frequented streets with brick. Ferries or *traghetti* for crossing the canals were also established as early as the 13th century; we find record of ferries at San Gregorio, San Felice, San Tomà, San Samuele, and so on, and also of longer ferries to the outlying islands like Murano and Chioggia, or to the mainland at Mestre and Fusina. The boatmen early erected themselves into gilds.

Gondolas.—The characteristic conveyances on the canals of Venice—which take the place of cabs in other cities—are the gondolas, flat-bottomed boats, some 30 ft. long by 4 or 5 ft. wide, curving out of the water at the ends, with ornamental bow and stern pieces and an iron beak (*ferro*), resembling a halberd, which is the highest part of the boat. The gondolier stands on a *poppa* at the stern with his face towards the bow, and propels the gondola with a single oar. There is a low cabin (*felze*) for passengers; the ordinary gondolas can take four or six persons, and larger ones (*barca* or *battello*) take eight. Gondolas are mentioned as far back as 1094, and, prior to a sumptuary edict passed by the great council in the 16th century, making black their compulsory colour, they were very different in appearance from now. Instead of the present boat, with its heavy black cabin and absence of colouring, the older forms had an awning of rich stuffs or gold embroideries, supported on a light arched framework open at both ends; this is the gondola still seen in Carpaccio's and Gentile Bellini's pictures (*c.* 1500). Since 1880 services of omnibus steamers (now municipal) have also been introduced.

Byzantine Architecture.—We can trace the continuous growth of Venice through the successive styles of Byzantine, Gothic, early Renaissance and late Renaissance architecture. The whole subject is magnificently treated in Ruskin's *Stones of Venice*. The two most striking buildings in Venice, St Mark's and the Doge's Palace, at once give us an example of the two earlier styles, the Byzantine and the Gothic, at least in their general design, though both are so capricious in development and in decoration that they may more justly be considered as unique specimens rather than as typical examples of their respective styles. In truth, owing to its isolated position on the very verge of Italy, and to its close connexion with the East, Venetian architecture was an independent development. Though displaying a preponderance of Oriental characteristics, it retained a quality of its own quite unlike the styles evolved by other Western countries.

The Byzantine style prevailed in Venice during the 11th and 12th centuries. The arches of this period are semicircular and usually highly stilted. Sculptured ornamentation, flowing scroll-work of semi-conventional foliage mingled with grotesque animals, birds or dragons, is freely applied to arches and string courses. The walls are built of solid brickwork and then covered with thin slabs of rich and costly marbles. Sculptured panels, with conventional motives, peacocks, eagles devouring hares, peacocks drinking from a cup on a tall pillar, are let into both exterior and interior walls, as are roundels of precious marbles, sawn from columns of porphyry, serpentine, verd antique, &c. The adoption of veneer for decoration prohibited any deep cutting, and almost all the sculpture is shallow. Only in the capitals, which are of extraordinary richness and variety, do we get any deep or bold relief. Dentil mouldings, of which examples may still be seen in the remains of the palace of Blachernae at Constantinople, are characteristic of Venetian ornamentation at this period, and remain a permanent feature in Venetian architecture down to the 11th century. The dome is the leading idea or motif in Byzantine ecclesiastical architecture; the domes are placed over square, not circular apartments, and their bases are brought to a circle by means of pendentives. In exterior elevation the chief effect is produced by the grouping of the domes. In the interior the effect is gained by broad masses of chromatic decoration in marble-veneer and mosaics on a gold ground to cover the walls and vaults, and by elaborate pavements of *opus sectile* and *opus Alexandrinum*. Owing to the marshy site the foundations of buildings in Venice offered considerable difficulties. A trench was dug in the soft upper mud until the stratum of stiff blue clay was reached. Piles of elm, oak, white poplar or larch were driven into this clay to the depth of 16 to 20 ft. or until absolute resistance was encountered. The heads of the piles were from 10 to 11 in. in diameter and they were driven in almost in contact. On this surface of pile heads was laid a platform of two layers of squared oak beams; and on this again the foundations proper were built. In some cases, however, as for example in the ducal palace itself, if the clay appeared sufficiently firm, the piles were dispensed with and the foundations went up directly from the oak platform which rested immediately on the clay. During the middle ages the walls of Venetian buildings were constructed invariably of brick. They were usually solid, but in some cases they were built *a sacco*—that is to say, two thin outer walls were built and the space between them was filled with grouted rubble. The delicate creamy Istrian stone, which is now so prominent a feature in Venetian architecture, did not come into common use till after the 11th century, when the Istrian coast became permanently Venetian. Before 1405 the mortar used in Venice was made of lime from Istria, which possessed no hydraulic qualities and was consequently very perishable, a fact which to a large extent accounts for the fall of the Campanile of San Marco. But when Venice took possession of the mainland her builders were able to employ a strong hydraulic dark lime from Albettone, which formed a durable cement, capable of resisting salt water and the corrosive sea air.

St Mark's.

The church of St Mark's, originally the private chapel of the doge, is unique among the buildings of the world in respect of its unparalleled richness of material and decoration. It grew with the growing state whose religious centre it was, and was adorned with the spoils of countless other buildings, both in the East and on the Italian mainland. A law of the republic required every merchant trading to the East to bring back some material for the adornment of the fane. Indeed, the building has been compared to the treasure den of a gang of "sea sharkers," and from a museum of sculpture of the most varied kind, nearly every century from the 4th down to the latest Renaissance being represented. The present church is the third on this site. Soon after the concentration at Rialto (see *History* below), a small wooden church was erected about the year 828 for the reception of the relics of St Mark, which had been brought from Alexandria when the Moslems pulled down the church where he was buried. St Mark then became the patron saint of Venice in place of St Theodore. This church was burned in 976 along with the ducal palace in the insurrection against the Doge Candiano IV. Pietro Orseolo and his successors rebuilt the church on a larger scale in the form of a basilica with three eastern apses and no transept, and Byzantine workmen were employed. As the state grew in wealth and importance the church grew with it. About the year 1063 the Doge Contarini resolved to remodel St Mark's. There can be no doubt that Byzantine artists had a large share in the work, but it is equally certain that Lombard workmen were employed along with the Orientals, and thus St Mark's became, as it were, a workshop in which two styles, Byzantine and Lombard, met and were fused together, giving birth to a new style, peculiar to the district, which may fairly be called Veneto-Byzantine.

In plan (see the article ARCHITECTURE) St Mark's is a Greek cross of equal arms, covered by a dome in the centre, 42 ft. in diameter, and by a dome over each of the arms. The plan is derived from the Church of the Holy Apostles at Constantinople, now covered by the mosque of Mahommed II., and bears a strong resemblance to the plan of St Front at Périgueux in France (1120). The addition of a narthex before the main front and a vestibule on the northern side brings the whole western arm of the cross to a square on plan. In elevation the façade seems to have connexion with the five-bayed façade of the Kahriyeh Jamè, or mosaic mosque, at Constantinople. The exterior façade is enriched with marble columns brought from Alexandria and other cities of the East, and bearing in many cases incised graffiti. Mosaics are employed to decorate the spandrils of the arches. Only one of the original mosaics now exists, the one over the doorway at the north-western, or St Alipio, angle. Its subject, which is of high historical value as a record of costume, represents the translation of the body of St Mark, and gives us a view of the west façade of the church as it was at the beginning of the 13th century before the addition of the ogee gables, with alternating crockets and statues, and the intermediate pinnacled canopies placed between the five great arches of the upper storey. The top of the narthex forms a wide gallery, communicating with the interior at the triforium level. In the centre of this gallery stand the four colossal bronze horses which belonged to some Graeco-Roman triumphal quadriga, and were brought to Venice by the Doge Enrico Dandolo after the fall of Constantinople in 1204; they were carried off by Napoleon to Paris in 1797, and restored by Francis of Austria in 1815.

Mosaic is the essential decoration of the church, and the architectural details are subordinated to the colour scheme. These mosaics belong to very various dates. The Doge Domenico Selvo began the decoration of the church in 1071, though it is uncertain whether any of his work can be now identified. The mosaics of the domes would seem to belong to the 12th century, probably before 1150. The mosaics of the atrium date from 1200 to 1300; the subjects are taken from Old Testament story. The baptistery mosaics represent the life of St John. The mosaics in the chapel of St Isidore (finished by Andrea Dandolo), giving us the life of the saint, were executed in 1355. In the sacristy is a series of 10th-century mosaics, and in other parts of the church are inferior and later mosaics from cartoons by later Venetian masters. Below the mosaics the walls and arches are covered with rare marbles, porphyries and alabaster from ancient columns sawn into slices and so arranged in broad bands as to produce a rich gamut of colour.

The eastern crypt, or *confessio*, extends under the whole of the choir and has three apses, like the upper church. The body of St Mark formerly rested here, but is now within the high altar. Below the nave is another crypt. The floors of both crypts have sunk considerably and are often under water; this settlement accounts for the inequalities of the pavement. The original part of the magnificent mosaic pavement probably dates from the middle of the 12th century, if we may judge from the pavement at Murano, exactly similar in style, material and workmanship, which bears the date 1140. The pavement consists partly of *opus Alexandrinum* of red and green porphyry mixed with marbles, partly of tesselated work of glass and marble tesserae.

The choir stands about 4 ft. above the nave and is separated from it by a marble rood-screen, on the architrave of which stand fourteen figures, the signed work of Jacobello and Pietro Paolo delle Masegne, 1394.

The Pala d'oro, or retable of the high altar, is one of the chief glories of St Mark's. It is one of the most magnificent specimens of goldsmiths' and jewellers' work in existence. It was ordered in 976 at Constantinople by the Doge Pietro I. Orseolo, and was enlarged and enriched with gems and modified in form, first by a Greek artificer in 1105, and then by Venetians between 1209 and 1345. It is composed of figures of Christ, angels, prophets and saints, in Byzantine enamel run into gold plates. It is about 11 ft. 6 in. wide, and about 4 ft. 8 in. high. It contains 1300 great pearls, 400 garnets, 90 amethysts, 300 sapphires, 300 emeralds, 15 rubies, 75 balas rubies, 4 topazes, 2 cameos; the gems, except where they have been replaced, are cut *en cabochon*. The treasury of St Mark's contains a magnificent collection of church plate and jewels.

Fine examples of Venetian Byzantine palaces—at least of the façades—are still to be seen on the Grand Canal and in some of the small canals. The interiors have been modified past recognition of their original disposition. The Byzantine palace seems to have had twin angle-towers—*geminas angulares turres*—such as those of the Ca' Molin on the Riva degli Schiavoni, where Petrarch lived. The restored (1880) Fondaco[1] dei Turchi (13th century), now the Museo Civico, also has two angle-towers. **Byzantine palaces.** The façades presented continuous colonnades on each floor with semicircular high stilted arches, leaving a very small amount of wall space. The buildings were usually battlemented in fantastic form. A good specimen may be seen in Lazzaro Sebastiani's picture of the piazzetta, in the Museo Civico. There on the right we see the handsome building of the old bakery, occupying the site of the present library; it has two arcades of Saracenic arches and a fine row of battlements. Other specimens still in existence are the municipal buildings, Palazzo Loredan and Palazzo Farsetti—if, indeed, these are not to be considered rather as Romanesque—and the splendid Ca' da Mosto, all on the Grand Canal. The richest ornamentation was applied to the arches and string courses, while plaques of sculpture, roundels and coats of arms adorned the façades. The remains of a Byzantine façade now almost entirely built into a wall in the Rio di Ca' Foscari offer us excellent illustration of this decorative work.

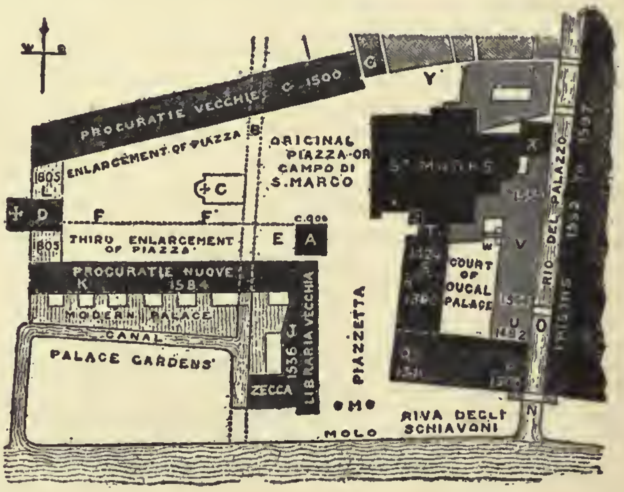

FIG. 1.—Square of St Mark and surrounding buildings. The original *campo* was bounded on the west by the canal B, with the 6th-century church of S. Geminiano, C, on its west bank. The first enlargement of the square was effected by Doge Sebastiano Ziani in 1176, when he filled up the canal and rebuilt the church on a new site at D, thus nearly doubling the size of the square. Lastly, the square was extended southwards in the 16th century, when the new palace of the procurators, K, was built by Scamozzi. Gentile Bellini's picture shows a line of houses along FF, reaching up to the great campanile, A. Napoleon I. in 1805–10 pulled down the church of S. Geminiano and built a new block at the west end of the square, L. The dates of the various parts of the existing ducal palace are indicated on the plan; the rebuilding was carried on in the following order, P, Q, R, S, T, U, V. At Z is the treasury of St Mark, which was originally one of the towers belonging to the old ducal palace; E, site of old houses; G, clock-tower; H, old palace of procurators; J, old library; M, two columns; N, Ponte della Paglia; O, Bridge of Sighs; W, Giants' Staircase; X, sacristy of St Mark; Y, Piazzetta.

Gothic Architecture.—Venetian Gothic, both ecclesiastical and domestic, shares most of the characteristics of north Italian Gothic generally, though in domestic architecture it displays one peculiarity which we shall presently note. The material, brick and terra-cotta, is the determining cause of the characteristics of north Italian Gothic

[1] This palace was originally the property of the Pesaro family, and afterwards of the duke of Este, and finally of the republic, which used it as a dwelling-place for royal guests before letting it to Turkish merchants. The word *Fondaco* (derived through Arabic from the Greek πανδοχεῖον), as applied to some of the Venetian palaces, denotes the mercantile headquarters of a foreign trading nation. Those still existing are the Turkish and the German (*F. de' Tedeschi*), the latter now converted into the post office.

Flatness and lack of deep shadows, owing to the impossibility of obtaining heavy cornices in that material, mark the style. The prevalence of sunlight led to a restriction of the windows and exaggeration of wall space. The development of tracery was hindered both by the material and by the relative insignificance of the windows. On the other hand, the plastic quality of terracotta suggested an abundance of delicate ornamentation on a small scale, which produced its effect by its own individual beauty without broad reference to the general scheme. Coloured marbles and frescoes served a like purpose. The exteriors of the north Italian Gothic churches are characterized by the flatness of the roof; the treatment of the west façade as a mere screen wall, masking the true lines of the aisle roofs; the great circular window in the west front for lighting the nave; the absence of pinnacles owing to the unimportance of the buttresses; the west-end porches with columns resting on lions or other animals. The peculiarity of Venetian domestic Gothic to which we have referred is this: we frequently find tracery used to fill rectangular, not arched, openings. The result is that the tracery itself has to support the structure above it—is, in fact, constructional—whereas in most other countries the tracery is merely, as it were, a pierced screen filling in a constructional arch. Hence the noticeable heaviness of Venetian tracery.

The ducal palace. The ducal palace, like St Mark's, is a symbol and an epitome of the race which evolved it. Soon after the concentration at Rialto the doge Angelo Particiaco began an official residence for the head of the state. It was probably a small, strongly fortified castle; one of its massive angle-towers is now incorporated in St Mark's and serves as the treasury. During the earlier years of the republic the ducal palace was frequently destroyed and rebuilt. It was burnt in 976 and again in 1106. At the close of the 12th century (1173–1179) Sebastian Ziani restored and enlarged the palace. Of his work some traces still remain in the richly sculptured bands built in at intervals along the 14th-century façade on the Rio, and part of the handsome larch-wood beams which formed the loggia of the piazzetta façade, still visible on the inner wall of the present loggia. The present magnificent building was a slow growth extending over three centuries and expanding gradually as the republic grew in riches.

The palace as we now see it was begun about 1300 by Doge Pietro Gradenigo, who soon after the closing of the great council gave its permanent form to the Venetian constitution. It is therefore, in a sense, contemporaneous with the early manhood of the state. Gradenigo built the façade along the Rio. About 1309 the arcaded façade along the lagoon front was taken in hand, and set the design for the whole of the external frontage of the palace. Towards the end of the 14th century, this façade, with its lower colonnade, upper loggia with handsome Gothic tracery, and the vast impending upper storey, which give to the whole building its striking appearance and audacious design, had been carried as far as the tenth column on the piazzetta side. At this point, perhaps out of regard for the remains of Ziani's palace, the work seems to have been arrested for many years, but in 1424 the building was resumed and carried as far as the north-west, or judgment, angle, near St Mark's, thus completing the sea and piazzetta façades as we now see them. The great gateway, the Porta della Carta, was added in 1439–42 from designs by Bartholomeo Buono (or Bon) and his son. The block of buildings in the interior, connecting the Porta della Carta to the Rio wing, was added about 1462 by the doge Cristoforo Moro. In 1479 a fire consumed the earlier buildings along the Rio, and these were replaced (1480–1550) by the present Renaissance structure.

The two main façades, those towards the sea and the piazzetta, consist of a repetition of the same design, that which was begun in the early years of the 14th century. The name of the architect who began the work and thus fixed the design of the whole is not certainly known, but it must have been a man of an earlier generation than that of Filippo Calendario, who is often stated to have been the chief architect of the older portion. Calendario was an accomplice in the conspiracy of Marino Faliero, and was executed together with the doge in 1355. It appears probable that a Venetian architect and sculptor named Pietro Baseggio was the chief master-builder in the first half of the 14th century. The design of these façades is very striking and unlike that of any other building in the world. It consists of two storeys with open colonnades, forming a long loggia on the ground and first floors, with seventeen arches on the sea front and eighteen on the other façade. Above this is a lofty third storey, pierced with a few large windows, with pointed arches once filled with tracery, which is now lost. The whole surface of the ponderous upper storey is covered with a diaper pattern in slabs of creamy white Istrian stone and red Verona marble, giving a delicate rosy-orange hue to the building. Very beautiful sculpture, executed with an ivory-like minuteness of finish, is used to decorate the whole building with wonderful profusion. At each of the three free angles is a large group immediately over the lower column. At the south-east angle is the "Drunkenness of Noah," at the south-west the "Fall of Man," and at the north-west the "Judgment of Solomon." Over each, at a much higher level, is a colossal figure of an archangel—Raphael, Michael and Gabriel.

The great internal court is surrounded with arcading. From the interior of the court access is given to the upper loggia by a very beautiful staircase of early Renaissance style, built in the middle of the 15th century by Antonio Rizzo. Two colossal statues of Neptune and Mars at the top of these stairs were executed by Jacopo Sansovino in 1554—hence the name "giants' staircase." Owing to a fire which gutted a great part of the palace in 1574, the internal appearance of the rooms was completely changed, and the fine series of early Paduan and Venetian paintings which decorated the walls of the chief rooms was lost. At present the magnificent council chambers for the different legislative bodies of the Venetian republic and the state apartments of the doges are richly decorated with gilt carving and panelling in the style of the later Renaissance. On the walls of the chief council chambers are a magnificent series of oil-paintings by Tintoretto and other less able Venetians—among them Tintoretto's masterpiece, "Bacchus and Ariadne," and his enormous picture of Paradise, the largest oil-painting in the world.

Gothic churches. Among the many Gothic churches of Venice the largest are the Franciscan church of Santa Maria Gloriosa dei Frari (1250–1280), and the Dominican church of SS. Giovanni e Paolo (1260–1400). The Frari is remarkable for its fine choir-stalls and for the series of six eastern chapels which from outside give a very good example of Gothic brickwork, comparable with the even finer apse of the now desecrated church of San Gregorio. The church of SS. Giovanni e Paolo was the usual burying-place of the doges, and contains many noble mausoleums of various dates. Besides these two churches we may mention Santo Stefano, an interesting building of central Gothic, "the best ecclesiastical example of it in Venice." The apse is built over a canal. The west entrance is later than the rest of the edifice and is of the richest Renaissance Gothic, a little earlier than the Porta della Carta.

Gothic palaces. But it is in the domestic architecture of Venice that we find the most striking and characteristic examples of Gothic. The introduction of that style coincided with the consolidation of the Venetian constitution and the development of Venetian commerce both in the Levant and with England and Flanders. The wealth which thus accrued found architectural expression in those noble palaces, so characteristic of Venice, which line the Grand and smaller canals. They are so numerous that we cannot do more than call attention to one or two.

The most striking example is undoubtedly the Ca' d' Oro, so called from the profusion of gold employed on its façade. It was built for Marino Contarini in 1421, rather a late period in the development of the style.

Marino kept a minute entry of his expenses, a document of the highest value, not merely for the history of the building, but also for the light it throws on the private life of the great patricians who gave to Venice such noble examples of art. Contarini was to some extent his own architect. He had the assistance of Marco d' Amadeo, a master-builder, and of Matteo Reverti, a Milanese sculptor, who were joined later on by Giovanni Buono and his son Bartolomeo. Other artists, of whom we know nothing else, such as Antonio Busetto, Antonio Foscolo, Gasparino Rosso, Giacomo da Como, Marco da Legno and others, were called in to help in evolving this masterpiece of decorated architecture, affording us an example of the way in which the ducal palace and other monuments of Venice grew out of the collaboration of numerous nameless artists. By the year 1431 the façade was nearly completed, and Contarini made a bargain with Martino and Giovanni Benzon for the marbles to cover what was yet unfinished. The façade is a triumph of graceful elegance; so light is the tracery, so rich the decoration, so successful the breach of symmetry which gives us a wing upon the left-hand side but none upon the right. But Contarini was not content to leave the marbles as they were. He desired to have the façade of his house in colour. The contract for this work, signed with Master Zuan de Franza, conjures up a vision of the Ca' d' Oro ablaze with colour and gleaming with the gold ornamentation from which it took its name.

Other notable examples of this style are the Palazzo Ariani at San Raffaelle, with its handsome window in a design of intersecting circles; the beautiful window with the symbols of the four Evangelists in the spandrils, in the façade of a house at San Stae; the row of three Giustinian palaces at S. Barnaba; the Palazzo Priuli at San Severo, with a remarkably graceful angle-window, where the columnar mullion carries down the angle of the wall; the flamboyant balconies of the Palazzo Contarini Fasan; the Palazzo Bernardo on a side canal near S. Polo, a late central Gothic building (1380–1400) which Ruskin describes as "of the finest kind and superb in its effect of colour when seen from the side. Taken as a whole, after the ducal palace this is the noblest effect of all in Venice."

Early Renaissance.—Towards the close of the 15th century Venetian architecture began to feel the influence of the classical revival; but, lying far from Rome and retaining still her connexion with the East, Venice did not fall under the sway of the classical ideals either so quickly or so completely as most Italian cities. Indeed, in this as in the earlier styles, Venice struck out a line for herself and developed a style of her own, known as Lombardesque, after the family of the Lombardi (Solari) who came from Carona on the Lake of Lugano and may be said to have created it.

The essential point about the style is that it is intermediary between Venetian Gothic and full Renaissance. We find it retaining some traces of Byzantine influence in the decorated surfaces of applied marbles, and in the roundels of porphyry and verd antique, while it also retained certain characteristics of Gothic, as, for instance, in the pointed arches of the Renaissance façade in the courtyard of the ducal palace designed by Antonio Rizzo (1499). Special notes of the style are the central grouping of the windows, leaving comparatively solid spaces on each side, which gives the effect of

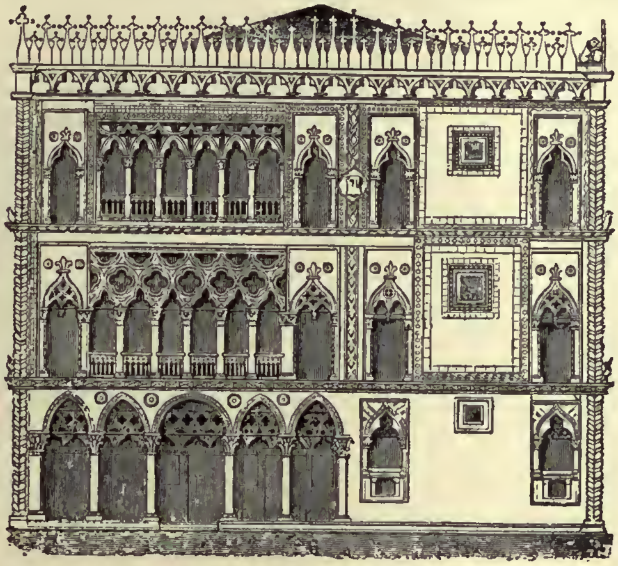

FIG. 2.—Ca' d' Oro, as originally built.

a main building with wings; the large amount of window space; the comparative flatness of the façades; the employment of a cornice to each storey; the effect of light and shade given by the balconies; and in churches by the circular pediments on the façades.

Churches. The most perfect example of this style in ecclesiastical architecture is the little church of the Miracoli built by Pietro Lombardo in 1480. The church is without aisles, and has a semicircular roof, and the choir is raised twelve steps above the floor of the nave. The walls, both internally and externally, are encrusted with marbles. The façade has the characteristic circular pediment with a large west window surrounded by three smaller windows separated by two ornamental roundels in coloured marble and of geometric design. Below the pediment comes an arcade with flat pilasters, which runs all round the exterior of the church. Two of the bays contain round-headed windows; the other three are filled in with white marble adorned by crosses and roundels in coloured marble. The lower order contains the flat pilastered portal with two panelled spaces on each side.

Similar results are obtained in the magnificent façade of the Scuola di San Marco, at SS. Giovanni e Paolo, which has six semicircular pediments of varying size crowning the six bays, in the upper order of which are four noble Romanesque windows. The lower order contains the handsome portal with a semicircular pediment, while four of the remaining bays are filled with quaint scenes in surprisingly skilful perspective. The façade of San Zaccaria (1457–1515), the stately design of Anton Marco Gambello and Mauro Coducci, offers some slight modifications in the use of the semicircular pediment, the line of the aisle roof being indicated by quarter-circle pediments abutting on the façade of the nave. San Salvadore, the work of Tullio Lombardo (1530), is severer and less highly ornamented than the preceding examples, but its plan is singularly impressive, giving the effect of great space in a comparatively small area. In this connexion we must mention the Scuola of S. Giovanni Evangelista at the Frari, with its fore-court and screen adorned by pilasters delicately decorated with foliage in low relief, and its noble staircase whose double flights unite on a landing under a shallow cupola. This also was the work of Pietro Lombardo and his son Tullio.

Palaces. Early Renaissance palaces occur frequently in Venice and form a pleasing contrast with those in the Gothic style. The Palazzo Dario with its dedication, *Urbis genio*, the superb Manzoni-Montecuculi-Polignac, with its friezes of spread-eagles in low relief, and the Vendramini-Calergi or *Non nobis* palace, whose façade is characterized by its round-headed windows of grouped twin lights between columns, are among the more important; though beautiful specimens, such as the Palazzo Trevisan on the Rio della Paglia, and the Palazzo Corner Reali at the Fava, are to be found all over the city.

Library of San Marco. *Later Renaissance.*—When we come to the fully developed Renaissance, architecture in Venice ceases to possess that peculiarly individual imprint which marks the earlier styles. It is still characterized by great splendour; indeed, the library of San Marco, built by Jacopo Sansovino in 1536, is justly considered the most sumptuous example of Renaissance architecture in the world. It is rich, ornate, yet hardly florid, distinguished by splendid effects of light and shade, obtained by a far bolder use of projections than had hitherto been found in the somewhat flat design of Venetian façades. The columned, round-headed windows are set in deeply between the pillars which carry the massive entablature, and this again is surmounted by a balustrade with obelisks at each angle and figures marking the line of each bay. The Istrian stone of which the edifice is built has taken a fine patina, which makes the whole look like some richly embossed casket in oxidized silver.

The full meaning of the change which had come over Venetian architecture, of the gulf which lies between the early Lombardesque style, so purely characteristic of Venice, and the fully developed classical revival, which now assumed undisputed sway, may best be grasped by comparing the old and the new Procuratie. Not more than eighty years separate these two buildings; the old Procuratie were built by Bartolomeo Buono about 1500, the new by Scamozzi in 1580, yet it is clear that each belongs to an entirely different world of artistic ideas. The Procuratie Vecchie is perhaps the longest arcaded façade in the world and certainly shows the least amount of wall space; the whole design is simple, the moulding and ornamentation severe. The Procuratie Nuove, which after all is merely Scamozzi's continuation of Sansovino's library, displays all the richness of that ornate building.

Churches. Among the churches of this period we may mention San Geminiano, designed by Sansovino, and destroyed at the beginning of the 19th century to make room for the ball-room built by Napoleon for Eugène Beauharnais. The churches of San Giorgio Maggiore and of the Redentore, a votive church for liberation from the plague, are both by Palladio. In 1632 Baldassare Longhena built the fine church of Santa Maria della Salute, also a votive church, erected by the state to commemorate the cessation of the plague of 1630. This noble pile, with a large and handsome dome, a secondary cupola over the altar, and a striking portal and flight of steps, occupies one of the most conspicuous sites in Venice on the point of land that separates the mouth of the Guidecca from the Grand Canal. In plan it is an octagon with chapels projecting one on each side. The volute buttresses, each crowned with a statue, add quaintly but happily to the general effect. After Longhena's date church architecture in Venice declined upon the dubious taste of baroque; the façades of San Moisè and of Santa Maria del Giglio are good specimens of this style.

Palaces. The palaces of the later Renaissance are numerous and frequently grandiose though frigid in design. The more remarkable are Sansovino's Palazzo Corner, Longhena's massive and imposing Palazzo Pesaro, the Palazzo Rezzonico, from designs by Longhena with the third storey added by Massari, Sammicheli's Palazzo Corner at San Polo, and Massari's well-proportioned and dignified Palazzo Grassi at San Samuele, built in 1740.

Modern Buildings.—In recent times the general prosperity of the city, which is on the ascendant, has brought about a revival of domestic and civic architecture. The architects Rupolo and Sardi have erected a considerable number of buildings, in which they have attempted, and with considerable success, to return either to Venetian Gothic or to the early Renaissance Lombardesque style. The most striking of these modern buildings are the new wing of the Hotel d'Italie, San Moisè, and the very successful fish market at Rialto, designed by Laurenti and carried out by Rupolo, in which a happy return to early Venetian Gothic has been effected in conjunction with a skilful adaptation of one of the most famous of the old houses of Venice, the Stalòn, or palace of the Quirini family.

Gild Halls.—Among the most remarkable buildings in Venice are the *scuole*, or gild halls, of the various confraternities. They were pious foundations created for mutual benefit and for purposes of charity. The *scuole* were divided into the six *scuole grandi*, so called from their numbers, wealth and privileges, and the *scuole minori* or *fraglie*, which in most cases were associated with an art or craft. The *scuole minori* were usually attached to some church in the quarter where the particular trade flourished. They had their special altar dedicated to the patron of the gild, a private burying-place, and a room in which they held their chapter. The six *scuole grandi*, San Teodoro, S. Maria della Carità, S. Giovanni Evangelista, San Marco, della Misericordia and San Rocco, on the other hand, built themselves magnificent gild halls. We have already mentioned two of these, the Scuola di San Giovanni Evangelista and the Scuola di San Marco, both of them masterpieces of the Lombardesque style. The Scuola di San Marco is now a part of the town hospital, and besides its façade, already described, it is remarkable for the handsome carved ceiling in the main hall (1463). Other beautiful ceilings are to be found in the great hall and the hall of the Albergo in the Scuola della Carità, now the Accademia. They are the work of Marco Cozzi of Vicenza and were executed between 1461 and 1464. The design of the former is a trellis crossing the ceiling diagonally; in each of the lacunae is carved a cherubim with eight wings; the figures and the trellis are gilded; the ground is a rich ultramarine. But the most magnificent of these gild halls is the Scuola di San Rocco, designed by Bartolomeo Buono in 1517 and carried out by Scarpagnino and Sante Lombardo. The façade on the Campo is large and pure in conception. The great staircase and the lower and upper halls contain the unrivalled series of paintings by Tintoretto, which called forth such unbounded enthusiasm on the part of Ruskin.

Campanili.—Among the more striking features of Venice we must reckon the *campanili* or bell-towers (see CAMPANILE). These were at one time more numerous than at the present day; earthquakes and subsidence of foundations have brought many of them down, the latest to fall being the great tower of San Marco itself, which collapsed on July 14th, 1902. Its reconstruction was at once undertaken, and completed in 1910. In a few other cases, for example at San Giorgio Maggiore, the fallen campanili were restored; but for the most part they were not replaced. The Venetian campanile usually stands detached from the church. It is almost invariably square; the only examples of round campanili in this part of Italy are to be found at Ravenna and at Caorle to the east of Venice; while inside Venice itself the solitary exception to the square plan was the campanile of San Paternian, built in 999 and now demolished, which was a hexagon. The campanile is usually a plain brick shaft with shallow pilasters running up the faces. It has small angle-windows to light the interior inclined plane or staircase, and is not broken into storeys with grouped windows as in the case of the Lombard bell-towers. Above the shaft comes the arcaded bell-chamber, frequently built of Istrian stone; and above that again the attic, either round or square or octagonal, carrying either a cone or a pyramid or a cupola, sometimes surmounted by a cross or a gilded angel which serves as a weathercock. Cressets used to be kept burning at night on some of the campanili to serve as beacons for those at sea. Among the existing campanili the oldest are San Geremia, dating from the 11th century, San Samuele from the 12th, San Barnaba and San Zaccaria from the 13th. The campanile of S. Giovanni Elemosinario at Rialto (1398–1400) is called by Ruskin "the most interesting piece of central Gothic remaining comparatively intact in Venice."

Public Monuments.—Venetian sculpture is for the most part ancillary to architecture; for example, Antonio Rizzo's "Adam" and "Eve" (1464), which face the giants'-staircase in the ducal palace, are parts of the decorative scheme; Sansovino's splendid monument to Tomaso Rangone is an essential feature of the façade of San Giuliano. The most successful Venetian sculpture is to be found in the many noble sepulchral private monuments. The jealousy of the Venetian republic forbade the erection of monuments to her great men. The sole exception is the superb equestrian statue in honour of the General Bartolomeo Colleoni, which stands on the Campo SS. Giovanni e Paolo. By his will Colleoni left his vast fortune to Venice on condition that a monument should be raised to him at St Mark's. He meant the great piazza, but by a quibble the republic evaded the concession of so unique an honour and claimed to have fulfilled the conditions of the bequest by erecting the monument at the Scuola of St Mark. The republic entrusted the work to the Florentine Verrocchio, who dying before the statue was completed begged the government to allow his pupil Lorenzo di Credi to carry it to a conclusion. The Venetians, however, called in Alessandro Leopardi, who cast the great equestrian group and added the pure and graceful pedestal. The monument was unveiled on the 21st of March 1496. Leopardo was also the creator (1505) of the three handsome bronze sockets in front of St Mark's which held the flagstaffs of the banners of Cyprus, Morea and Crete, when the republic was mistress of those territories.

By the side of the sea in the piazzetta, on to which the west façade of the ducal palace faces, stand two ancient columns of Egyptian granite, one red and the other grey. These great monoliths were brought as trophies to Venice by Doge Domenico Michieli in 1126, after his victories in Syria. In 1180 they were set up with their present fine capitals and bases by a Lombard engineer, Niccolo de' Barattieri. The grey column is surmounted by a fine bronze lion of Byzantine style, cast in Venice for Doge Ziani about 1178 (this was carried off to Paris by Napoleon in 1797, and sent back in pieces in 1816; but in 1893 it was put together again); and in 1329 a marble statue of St Theodore, standing upon a crocodile, was placed on the other column. Among modern monuments the most successful is that to Goldoni at San Bartolomeo near the Rialto. It is the work of the sculptor dal Zotto.

Institutions.—Perhaps the most famous institution of Venice is the arsenal, whose history and activity has continued unbroken from the earliest days of the republic down to the present time.

The arsenal. The arsenal was founded about the year 1104 by the doge Ordelap Falier. Before that date Venetian shipping was built at the spot near the piazzetta, known as the *terra nova*, where the royal gardens now are. The arsenal, which was famous in Dante's day, received its first enlargement in 1304, when, on the design of Andrea Pisano, new building sheds and the rope walk or *Tana* were erected. Pisano's building sheds, nine in a row, with peculiarly shaped roofs, were still standing intact—one of the most interesting medieval monuments of Venice—until recently, but they have been modified past recognition. In 1325 the second addition, the *arsenale nuovo*, was made, and a third, the *arsenale nuovissimo*, in 1473; a fourth, the *Riparto delle Galeazze*, about 1539; and in 1564 the fifth enlargement, the *Canal delle Galeazze e Vasca*, took place. After the fall of the republic the arsenal continued to occupy the attention of the various governments. In 1810 the site of the suppressed convent and church of the Celestia was added. The entire circuit of the arsenal, about two miles in extent, is protected by a lofty wall with turrets. The main door of the arsenal is the first example in Venice of the purely classical style. It is a noble portal, erected in 1460, apparently from designs by Fra Giocondo, with the lion of St Mark in the attic. The statuary, with Sta Giustina on the summit of the tympanum, was added in 1571 and 1578. The whole design was modified in 1688 so as to represent a triumphal arch in honour of Morosini Peloponnesiaco, who brought from Athens to Venice the four lions in Pentelic marble which now stand before the gate. (On the largest of these lions is cut a runic inscription recording an attack on the Piraeus in the 11th century by Norse warriors of the Varangian guard, under Harold Hardrada, afterwards—1047—king of Norway.) The arsenal suffered frequently and severely from fires, the worst being those of 1509 and 1569; yet such was the wealth of Venice that in the following year she put upon the seas the fleet that crushed the Turks at Lepanto in 1571.

The Lido. The Lido, which lies about 2 m. S.E. of Venice and divides the lagoon from the sea, is rapidly becoming a fashionable bathing-place. The point of San Nicolò del Lido is strongly fortified to protect the new entrance to the port (see harbour). Inside the fortress lies the old Protestant burying-ground, with tombs of Sackville, of John Murray, of Sir Francis Vincent, last ambassador but one from Great Britain to the republic, of Consul Smith, whose collection of books forms the nucleus of the King's library in the British Museum, and of Catherine Tofts, the singer, Smith's first wife. At Sant' Elisabetta is the bathing establishment.

Libraries.—The library of San Marco contains upwards of 35,000 printed volumes and about 10,000 manuscripts. The library is said to owe its origin to Petrarch's donation of his books to the republic. Most of these have now disappeared. In 1635 Fra Fortunato Olmo found in a room over the great door of St Mark's a number of books which he supposed to be Petrarch's gift. He sent a list to Tomasini, who published it in his *Petrarca Redivivus* (Patavii, 1635). These codices passed to the Marciana, and Zanetti catalogued them as the *Fondo antico*. It is very doubtful whether these books really belonged to Petrarch. We may date the true foundation of the library to the donation of Cardinal Bessarion. Bessarion had intended to bequeath his books to the Benedictines of San Giorgio Maggiore, but Pietro Morosini, Venetian ambassador at Rome, pointed out the inconvenience of housing his library on an island that could not easily be reached. The cardinal therefore obtained a bull from Pope Paul II., permitting him to recall his original donation, and in a letter dated from the baths of Viterbo, May 13th, 1468, he made over his library to the republic. The principal treasures of the collection, including splendid Byzantine book-covers, the priceless codices of Homer, the Grimani Breviary, an early Dante, &c., are exhibited under cases in the Sala Bessarione in the Zecca or mint where the library has been installed. Another library was left to the public by the munificence of Count Quirini-Stampalia, who bequeathed his collections and his house at Santa Maria Formosa to be held in trust for students. The state archives are housed in the Franciscan monastery at the Frari. They contain the voluminous and invaluable records of the Venetian republic, diplomatic, judicial, commercial, notarial, &c. Under the republic the various departments of state stored their records in various buildings, at the ducal palace, at the Scuola di San Teodoro, at the Camerlenghi. The Austrian government gathered all these into one building and arranged the vast masses of papers in fairly convenient order. Though the state papers of Venice have suffered from fire and the series begins comparatively late, yet their fullness and the world-wide sweep of Venetian interests render this collection an inexhaustible storehouse of data for students. Among other learned institutions we may mention the Ateneo Veneto, the Deputazione per la Storia Patria, and the Royal Institute of Science, Letters and Art, which has its seat in the Palazzo Loredan at Santo Stefano.

Harbour.—Under the republic commercial shipping used to enter Venice by the port of San Nicolò del Lido and lie along the quay called the Riva degli Schiavoni, in the basin of San Marco, and up the broad Giudecca Canal. But with the decline of Venice the trade of the port fell off; the mouth of the Lido entrance became gradually silted up owing to the joint action of the tide and the current, and for many years complete stagnation characterized the port. Under Austrian rule a revival began, which has been continued and intensified since Venice became part of united Italy. When the railway bridge brought Venice into touch with the mainland and the rest of Europe, it became necessary to do something to reopen the harbour to larger shipping. The Austrians, abandoning the nearer Lido entrance to the lagoons, resolved to deepen and keep open the Malamocco entrance. This is 8 m. distant from Venice, and can only be reached by a long and tortuous channel across the lagoon, whose course is marked out by those groups of piles which are so characteristic a feature of the lagoon landscape. The channel required constant dredging and was altogether inconvenient; yet for many years it remained the main sea approach to Venice. A dock was constructed at the western or farther end of the Giudecca Canal, near the railway. The unification of Italy, the growing prosperity of the country, above all the opening of the Suez Canal, which restored to Venice the full value of her position as the port farthest into the heart of Europe, brought about an immense expansion of trade. The government accordingly resolved to reopen the Lido entrance to the lagoon, and thus to afford a shorter and more commodious access from the sea. As at the Malamocco entrance so at the Lido, two moles were run out in a south-westerly direction; the westerly is about 2 m., the easterly about 3 m. in length. The natural scour thus created has given a depth of 26 ft. of water through the sand-bank. The mean rise and fall of the tide is about 2 ft., but under certain conditions of wind the variation amounts to 5 ft. and over. The health of the city depends, of course, to a large extent on this ebb and flow. The government also turned its attention to the inadequate accommodation at the docks, and proposals for a new quay on the western side of the present basin, and for a second basin 900 yds. long and 170 yds. wide, were the result.

Trade.—A comparison between the exports and imports of the years 1886 and 1905 will give an exact idea of the rate at which the port of Venice developed. In 1886 the total value of exports to foreign countries amounted to £7,239,479; of imports, £8,788,012. In 1905 the exports to foreign countries valued £11,650,932, the imports £13,659,306. As has been the case throughout her history, the trade of Venice is still mainly a transit trade. Wheat, coal, cotton, petroleum, wood, lime and cement are brought into Venice for shipment to the Levant or for distribution over Italy and Europe.

Venice became very celebrated in the 15th century for textiles. Its damasks and other silk stuffs with patterns of extraordinary beauty surpassed in variety and splendour those of the other chief centres of silk-weaving, such as Florence and Genoa. In addition to the native stuffs, an immense quantity of costly Oriental carpets, wall-hangings and other textiles was imported into Venice, partly for its own use, and partly for export throughout western Europe. On occasions of festivals or pageants the balconies, the bridges, the boats, and even the façades of the houses, were hung with rich Eastern carpets or patterned textiles in gold and coloured silk. The glass manufactory of Murano (*q.v.*), a small island about $1\frac{1}{2}$ m. to the north of Venice, was a great source of revenue to the republic. Glass drinking cups and ornamental vessels, some decorated with enamel painting, and "silvered" mirrors were produced in great quantities from the 14th century downwards, and exported. Like many other arts in Venice, that of glass-making appears to have been imported from Moslem countries, and the influence of Oriental design can be traced in much of the Venetian glass. The art of making stained-glass windows was not practised by the Venetians; almost the only fine glass in Venice is that in a south transept window in the Dominican church, which, though designed by able Venetian painters, is obviously the work of foreigners.

The ancient glass-bead industry (*conterie*), which some years since suffered severely from over-production, has now regained its position through the union of the different factories, by which the output is controlled in such a way as to render trade profitable. Venetian beads are now sent in large quantities to the various colonies in Africa, and to India, Sumatra and Borneo. Similarly, the glass industry has revived. New amalgams and methods of colouring have been discovered, and fresh forms have been diligently studied. Special progress has been made in the production of mirrors, electric lamps, candelabra and mosaics. New industries are those of tapestry, brocades, imitation of ancient stuffs, cloth of silver and gold, and Venetian laces. The secret of lace-making was believed to have been lost, but the late Signor Fambri discovered at Chioggia an old woman who knew it, and placed her at the head of a lace school. Fambri was ruined by his enterprise, but other manufacturers, more expert than he, drew profit from his initiative, and founded flourishing factories at Pellestrina and Burano. Other important industries are wood-carving (of an artistic excellence long unknown), artistic iron-working, jewelling, bronze-casting, the production of steam-engines, machinery, matches (largely exported to Turkey, Egypt, Russia, Austria-Hungary and Greece), clock-making, wool-weaving and the manufacture of chemical manures.

Population.—In 1548 the population of Venice numbered 158,069; in 1607–29, 142,804; in 1706, 140,256; in 1785, 139,095; in 1881, 132,826. The municipal bulletin of the 31st of December 1906 gives a total of 169,563, not including 4835 soldiers.

Administration.—Venice is administered by a prefect representing the crown and responsible to the central government at Rome, from whom he receives orders. Under his cognizance come questions of public order, health and elections to parliament. The two arms of the police, the Carabinieri and the Publica Sicurezza, are at his disposal. Purely local matters, however, are in the hands of the municipio or town council. At the head of the town council is the Sindaco or mayor, elected by the council itself.

Under the republic, and until modern times, the water supply of Venice was furnished by the storage of rain-water supplemented by water brought from the Brenta in boats. The famous Venetian *pozzi*, or wells for storing rain-water from the roofs and streets, consisted of a closed basin with a water-tight stratum of clay at the bottom, upon which a slab of stone was laid; a brick shaft of radiating bricks laid in a permeable jointing material of clay and sand was then built. At some distance from the shaft a square water-tight wall was built, and the space between it and the shaft was filled in with sand, which was purified of all saline matter by repeated washings; on the ground-level perforated stones set at the four corners of the basin admitted the rain-water, which was discharged from the roofs by lead pipes; this water filtered through the sand and percolated into the shaft of the well, whence it was drawn in copper buckets. The present water supply, introduced in 1884, is brought from the commune of Trebaseleghe, where it is collected from 120 artesian wells. It is carried under the lagoon to Sant' Andrea, where the reservoirs are placed.

Of the 19,000 houses in Venice only 6000 have drains and sinks, all the others discharge sewage through pipes directly or indirectly into the canals. With the rise and fall of the tide the discharge pipes are flushed at the bottom. An important investigation undertaken by the Bacterioscopical Laboratory, with regard to the pollution of the Venetian canals by the city sewage, led to the discovery that the water of the lagoons possesses auto-purifying power, not only in the large canals but even in the smallest ramifications of the waterways. The investigation was carried out with scrupulous scientific rigour upon samples of water taken in every part of the city, at all states of the tide and under various atmospheric conditions.

The church is ruled by the patriarch of Venice, the metropolitan of the province formed by the Veneto. The patriarch of Venice is usually raised to the purple. The patriarchate dates from 1451, when on the death of Domenico Michiel, patriarch of Grado, the seat of that honour was transferred from desolate and insalubrious Grado to the cathedral church of Castello in Venice, and Michiel's successor, Lorenzo Giustinian, assumed the title of patriarch of Venice. On the fall of the republic St Mark's became the cathedral church of the patriarch. There are thirty parishes in the city of Venice and fifteen in the lagoon islands and on the littoral.

In recent times there has been a good deal of activity in Venice in regard to the preservation of its artistic and architectural treasures. Some of the earlier activity was unfortunately misplaced. St Mark's suffered on two occasions: first during the restoration of the north façade in 1843, and again during that of the south façade, begun in 1865 and finished in 1878. The latter façade was completely reconstructed upon 2200 piles driven to great depths, with the result that the general harmony of the monument—the effect of time and of atmospheric conditions—was completely lost. A lively agitation all over Europe, and particularly in England (conducted by Ruskin and William Morris), led the Italian government to discard the Austrian plan of restoration, at least as regards the interior of the Basilica, and to respect the ancient portions which had stood the test of time and had escaped "renewal" by man. In 1880 a Vigilance Committee was appointed to watch over the restoration of the interior. The committee secured much *verde antico* and porphyry for the restoration of the pavement, in place of the common marbles which it had been intended to use, and organized special workshops for the restoration and preservation of the ancient mosaics, which it had been intended to detach and replace. Pieces already detached were restored to their original positions, and those blackened by damp and dust were carefully cleaned. Breaks were filled up with cubes obtained from fragments of contemporary mosaics previously demolished. In this way the mosaics of the two arches of the atrium and those of the Zeno chapel were cleaned and preserved.

Contemporaneously with the restoration of the southern façade of St Mark's, the restoration of the colonnade of the ducal palace towards the Piazzetta and the Mole was undertaken at a cost of £23,000. The chief work was executed at the south-west angle, where the columns of the arcade had become so broken and distorted as to menace the safety of the whole building. The corner towards the Ponte della Paglia was also restored, and the hideous device of walling up the five last arches, adopted in the 16th century by the architect Da Ponte, was removed without prejudice to the stability of the structure. In order to lighten the palace the Venetian Institute of Science, Letters and Arts removed its headquarters and its natural history collection to Santo Stefano. For the same reason the Biblioteca Marciana with its 350,000 volumes was moved to the Old Mint, opposite the ducal palace. The space thus cleared has been used for the rearrangement of the Archaeological and Artistic Museum. Side by side with these changes has proceeded the reorganization of the Royal Gallery of Ancient Art, which, created by Napoleon I. for the students of the adjoining Academy of Fine Arts, gradually acquired such importance that in 1882 the government divided it from the academy and rendered it autonomous. The gallery now constitutes a unique collection of Venetian paintings from the most ancient artists down to Tiepolo, one hall only being reserved for other Italian schools and one for foreign schools. Altogether the gallery contains twenty rooms, one being assigned to the complete cycle of the "History of Saint Ursula," by Carpaccio; another to Giambellino and to the Celliniani; and a whole wall of a third being occupied by the famous Veronese, "Il Convito in casa di Levi." Titian's "Presentazione al Tempio," painted for the Scuola della Carita, which is now the seat of the gallery, has been placed in its original position. The hall of the Assumption has been left untouched. Nineteenth-century pictures have been eliminated as foreign to the character of the collection, and inferior works relegated to a side passage. The reorganization of the Archaeological and Artistic Museum and of the Royal Gallery of Ancient Art coincided with the inauguration in April 1895 of a series of biennial International Art Exhibitions, arranged in order to celebrate the silver wedding of the king and queen of Italy. A special brick structure was erected in the public gardens to receive the works of contemporary artists, both Italian and foreign. The selection of works was made by an international jury from which Venetian artists were excluded. The second exhibition, visited by 336,500 persons, was held in 1897, and a third in 1899. The success of this exhibition (visited by 407,930 persons) led to the organization of a fourth exhibition in 1901, largely devoted to the works of Ruskin. The institution of these exhibitions furnished Prince Giovanelli with an opportunity to found at Venice a Gallery of Modern Art, for which a home was found in the Palazzo Pesaro, bequeathed to the city by Princess Bevilacqua la Masa.

History.—It is usually affirmed that the state of Venice owes its origin to the barbarian invasions of north Italy; that it was founded by refugees from the mainland cities who sought asylum from the Huns in the impregnable shallows and mud banks of the lagoons; and that the year 452, the year when Attila sacked Aquileia, may be taken as the birth-year of Venice. That is true in a measure. Venice, like Rome and other famous cities, was an asylum city. But it is nearly certain that long before Attila and his Huns swept down upon the Venetian plain the little islands of the lagoon already had a population of poor but hardy fisherfolk living in quasi-independence, thanks to their poverty and their inaccessible site. This population was augmented from time to time by refugees from the mainland cities of Aquileia, Concordia, Opitergium Altinum and Patavium. But these did not mingle readily with the indigenous population; as each wave of barbarian invasion fell back, these refugees returned to their mainland homes, and it required the pressure of many successive incursions to induce them finally to abandon the mainland for the lagoon, a decision which was not reached till the Lombard invasion of 568. On each occasion, no doubt, some of the refugees remained behind in the islands, and gradually built and peopled the twelve lagoon townships, which formed the germ of the state of Venice and were subsequently concentrated at Rialto or in the city we now know as Venice. These twelve townships were Grado, Bibione, Caorle, Jesolo, Heraclea, Torcello, Murano, Rialto, Malamocco, Poveglia, Chioggia and Sottomarina. The effect of the final Lombard invasion is shown by the resolve to quit the mainland and the rapid building of churches which is recorded by the *Cronaca altinate.* The people who finally abandoned the mainland and took their priests with them are the people who made the Venetian republic. But they were not as yet a homogeneous population. The rivalries of the mainland cities were continued at closer quarters inside the narrow circuit of the lagoons, and there was, moreover, the initial schism between the indigenous fisher population and the town-bred refugees, and these facts constitute the first of the problems which now affronted the growing community: the internal problem of fusion and development. The second problem of prime importance was the external problem of independence. The early history of the republic is chiefly concerned with the solution of these two problems.

To take the problem of independence first. There is little doubt that the original lagoon population depended for its administration, as far as it had any, upon the larger cities of the mainland. There is a tradition that Venice was founded by "consuls from Padua"; and Padua claimed complete control of the course of the Brenta down to its mouth at Malamocco. The destruction of the mainland cities, and the flight of their leading inhabitants to the lagoons, encouraged the lagoon population to assert a growing independence, and led them to advance the doctrine that they were "born independent." Their development as a maritime people, engaged in small trading and intimately acquainted with their home waters, led Belisarius to seek their help in his task of recovering Italy from the Goths. He was successful; and the lagoons became, theoretically at least, a part of the Eastern empire. But the empire was vast and weak, and its capital lay far away; in practice, no doubt, the lagoon population enjoyed virtual independence, though later the Byzantine claim to suzerainty became one of the leading factors in the formation of the state. It was from Byzantium that the Venetian people received the first recognition of their existence as a separate community. Their maritime importance compelled Narses, the imperial commander, to seek their aid in transporting his army from Grado; and when the Paduans appealed to the Eunuch to restore their rights over the Brenta, the Venetians replied by declaring that islands of the lagoon and the river mouths that fell into the estuary were the property of those who had rendered them habitable and serviceable. Narses declined to intervene, Padua was powerless to enforce its claims and Venice established a virtual independence of the mainland. Nor was it long before Venice made a similar assertion to the imperial representative, Longinus. He was endeavouring to treat with Alboin and the Lombards, and desired to assure himself of Venetian support. He invited the Venetians to give him an escort to Constantinople, which they did, and also to acknowledge themselves subjects of the empire. But they replied that "God who is our help and protector has saved us that we might dwell upon these waters. This second Venice which we have raised in the lagoons is our mighty habitation; no power of emperor or of prince can touch us." That was an explicit statement of Venetian aims and contentions: the place and people had made each other and now belonged exclusively to each other. Longinus admitted that the Venetians were indeed "a great people with a strong habitation"; but by dint of promising large concessions and trading privileges, he induced the Venetians to make an act of submission—though not upon oath. The terms of this pact resulted in the first diploma conferred on Venice as a separate community (584). But it was inevitable that, when the barbarians, Lombard or Frank, were once established on the mainland of Italy, Venice should be brought first into trading and then into political relations with their near neighbours, who as masters of Italy also put forward a claim to sovereignty in the lagoons. It is between the two claims of east and west that Venice struggled for and achieved recognized independence.

Turning to the other problem, that of internal fusion and consolidation, we find that in 466, fourteen years after the fall of Aquileia, the population of the twelve lagoon townships met at Grado for the election of one tribune from each island for the better government of the separate communities, and above all to put an end to rivalries which had already begun to play a disintegrating part. But when the lagoon population was largely augmented in 568 as the result of Alboin's invasion, these jealousies were accentuated, and in 584 it was found expedient to appoint twelve other tribunes, known as the *Tribuni Majores*, who formed a kind of central committee to deal with all matters affecting the general weal of the lagoon communities. But the *Tribuni Majores* were equally powerless to allay the jealousies of the growing townships which formed the lagoon community. Rivalry in fishing and in trading, coupled with ancient antipathies inherited from the various mainland cities of origin, were no doubt the cause of these internecine feuds. A crisis was reached when Christopher, patriarch of Grado, convened the people of the lagoon at Heraclea, and urged them to suppress the twelve tribunes and to choose a single head of the state. To this they agreed, and in 697 Venice elected her first doge, Paulo Lucio Anafesto.

The growing importance of the lagoon townships, owing to their maritime skill, their expanding trade, created by their position between east and west, their monopoly of salt and salted fish, which gave them a strong position in the mainland markets, rendered it inevitable that a clash must come over the question of independence, when either east or west should claim that Venice belonged to them; and inside the lagoons the growing prosperity, coupled with the external threat to their liberties, concentrated the population into two well-defined parties—what may be called the aristocratic party, because it leaned towards imperial Byzantium and also displayed a tendency to make the dogeship hereditary, and the democratic party, connected with the original population of the lagoons, aspiring to free institutions, and consequently leaning more towards the church and the Frankish kingdom which protected the church. The aristocratic party was captained by the township of Heraclea, which had given the first doge, Anafesto, to the newly formed community. The democratic party was championed first by Jesolo and then by Malamocco.

The advent of the Franks determined the final solution. The emperor Leo, the Isaurian, came to open rupture with Pope Gregory II. over the question of images. The pope appealed to Liutprand, the powerful king of the Lombards, to attack the imperial possessions in Ravenna. He did so, and expelled the exarch Paul, who took refuge in Venice and was restored to his post by the doge of the Heraclean or Byzantine party, Orso, who in return for this assistance received the imperial title of *hypatos*, and trading rights in Ravenna. The pope, however, soon had cause for alarm at the spread of the Lombard power which he had encouraged. Liutprand proceeded to occupy territory in the Ducato Romano. The pope, looking about for a saviour, cast his eyes on Charles Martel, whose victory at Tours had riveted the attention of the world. Charles's son, Pippin, was crowned king of Italy, entered the peninsula at the head of the Franks, defeated the Lombards, took Ravenna and presented it to the pope, while retaining a feudal superiority. Desiderius, the last Lombard king, endeavoured to recover Ravenna. Charlemagne, Pippin's son, descended upon Italy, broke up the Lombard kingdom (774), confirmed his father's donation to the pope, and in reprisals for Venetian assistance to the exarch, ordered the pope to expel the Venetians from the Pentapolis. Venice was now brought face to face with the Franks under their powerful sovereign, who soon showed that he intended to claim the lagoons as part of his new kingdom. In Venice the result of this menace was a decided reaction towards Byzantium. In opposition to the Frankish claim, Venice resolved to affirm her dependence on the Eastern empire. But the democratic party, the Frankish party in Venice, was powerful. Feeling ran high. A crisis was rapidly approaching. The Byzantine Doge Giovanni Galbaio attacked Grado, the see of the Francophil Patriarch Giovanni, captured it, and flung the bishop from the tower of his palace. But the murdered patriarch was succeeded by his no less Francophil nephew Fortunatus, a strong partisan, a restless and indomitable man, who along with Obelerio of Malamocco now assumed the lead of the democratic party. He and his followers plotted the murder of the doge, were discovered, and sought safety at the court of Charlemagne, where Fortunatus strongly urged the Franks to attack the lagoons.

Meantime the internal politics of Venice had been steadily preparing the way for the approaching fusion at Rialto. The period from the election of the first doge to the appearance of the Franks was characterized by fierce struggles between Heraclea and Jesolo. At length the whole population agreed to fix their capital at Malamocco, a compromise between the two incompatible parties, marking an important step towards final fusion at Rialto.

That central event of early Venetian history was reached when Pippin resolved to make good his title as king of Italy. He turned his attention to the lagoon of Venice, which had been steadily growing in commercial and maritime importance, and had, on the whole, shown a sympathy for Byzantium rather than for the Franks. Pippin determined to subdue the lagoons. He gathered a fleet at Ravenna, captured Chioggia, and pushed on up the Lido towards the capital of the lagoons at Malamocco. But the Venetians, in face of the danger, once more removed their capital, this time to Rialto, that group of islands we now call Venice, lying in mid-lagoon between the *lidi* and the mainland. This step was fatal to Pippin's designs. The intricate water-ways and the stubborn Venetian defence baffled all his attempts to reach Rialto; the summer heats came on; the Lido was unhealthy. Pippin was forced to retire. A treaty between Charlemagne and Nicephorus (810) recognized the Venetians as subjects of the Eastern empire, while preserving to them the trading rights on the mainland of Italy which they had acquired under Liutprand.

The concentration at Rialto marks the beginning of the history of Venice as a full-grown state. The external menace to their independence had welded together the place and the people; the same pressure had brought about the fusion of the conflicting parties in the lagoon townships into one homogeneous whole. There was for the future one Venice and one Venetian people dwelling at Rialto, the city of compromise between the dangers from the mainland, exemplified by Attila and Alboin, and the perils from the sea, illustrated by Pippin's attack. The position of Venice was now assured. The state was a vassal of a weak and distant empire, which would leave it virtually free to pursue its own career; it was an independent tributary of a near and powerful kingdom with which it could trade, and trade between east and west became henceforth the note of its development.

The first doge elected in Rialto was Angelo Particiaco, a Heraclean noble, with a strong bias towards Byzantium, and his reign was signalized by the building of the first church of San Marco, and by the translation of the saint's body from Alexandria, as though to affirm and to symbolize the creation of united Venice.

The history of Venice during the next two hundred years is marked externally by the growth of the city, thanks to an ever-expanding trade, both down the Adriatic, which brought the republic into collision with the Dalmatian pirates and led to their final conquest, in 1000, by the doge Pietro Orseolo II., and also on the mainland, where Venice gradually acquired trading rights, partly by imperial diploma, partly by the establishment and the supply of markets on the mainland rivers, the Sile and the Brenta. Internally this period is characterized by the attempt of three powerful families, the Particiachi, the Candiani and the Orseoli, to create an hereditary dogeship, and the violent resistance offered by the people. We find seven of the Particiachi, five Candiani and three Orseoli reigning in almost unbroken succession, until, with the ostracism of the whole Orseolo family in 1032, the dynastic tendency was crushed for ever. During the same period we also note the development of certain families, thanks to the accumulation of wealth by trade, and here we get the beginnings of that commercial aristocracy whose evolution was the dominant factor in the constitutional history of the republic.

The growing wealth of Venice soon attracted the cupidity of her piratical neighbours on the coast of Dalmatia. The swift Liburnian vessels began to raid the Lido, compelling the Venetians to arm their own vessels and thus to form the nucleus of their famous fleet, the importance of which was recognized by the Golden Bull of the emperor Basil, which conferred on Venetian merchants privileges far more extensive than any they had hitherto enjoyed, on condition that the Venetian fleet was to be at the disposition of the emperor. But the Dalmatian raids continued to harass Venetian trade, till, in 1000, the great doge Pietro Orseolo II. attacked and captured Curzola and stormed the piratical stronghold of Lagosta, crushing the freebooters in their citadel. The doge assumed the title of duke of Dalmatia, and a great step was taken towards the supremacy of Venice in the Adriatic, which was essential to the free development of her commerce and also enabled her to reap the pecuniary advantages to be derived from the Crusades. She now commanded the route to the Holy Land and could supply the necessary transport, and from the Crusades her growing aristocracy reaped large profits. Orseolo's victory was commemorated and its significance affirmed by the magnificent symbolical ceremony of the "wedding of the sea" (*Sposalizio del Mar*), celebrated henceforward every Ascension day. The result of the first three Crusades was that Venice acquired trading rights, a Venetian quarter, church, market, bakery, &c., in many of the Levant cities, *e.g.* in Sidon (1102) and in Tyre (1123). The fall of Tyre marks a great advance in development of Venetian trade; the republic had now passed beyond the Adriatic, and had taken an important step towards that complete command of the Levant which she established after the Fourth Crusade.

This expansion of the trade of Venice resulted in the rapid development of the wealthier classes, with a growing tendency to draw together for the purpose of securing to themselves the entire direction of Venetian politics in order to dominate Venetian commerce. To achieve their object, a double line of conduct was imposed upon them: they had to absorb the powers of the doge, and also to deprive the people of the voice they possessed in the management of state affairs by their presence in the *concione* or general assembly of the whole community, which was still the fountain of all authority. The first step towards curtailing the power of the doge was taken in 1032, when the family of the Orseoli was finally expelled from Venice and the doge Domenico Flabianico was called to the throne. A law was then passed forbidding for the future the election of a doge-consort, a device by which the Particiachi, the Candiani and the Orseoli had each of them nearly succeeded in carrying out their dynastic ambitions. Further, two ducal councillors were appointed to assist the doge, and he was compelled, not merely permitted, to seek the advice of the more prominent citizens at moments of crisis. By this reform two important offices in the Venetian constitution—the privy council (*consiglieri ducali*) and the senate (the *pregadi* or invited)—came into being. Both were gradually developed on the lines desired by the aristocracy, till we reach the year 1171.

The growth of Venetian trade and wealth in the Levant roused the jealousy of Genoa and the hostility of the imperial court at Constantinople, where the Venetians are said to have numbered 200,000 and to have held a large quarter of the city in terror by their brawls. The emperor Manuel I., urged on by the Genoese and other rivals of Venice, seized the pretext. The Venetians were arrested and their goods confiscated. Popular feeling at Venice ran so high that the state was rashly swept into war with the empire. To provide the requisite funds for this vast undertaking; a forced loan of 1% on net incomes was raised; the money bore interest at the rate of 4%. The bonds were negotiable, and afford us the earliest instance of the issue of government stock. The doge Vitale Michiel II. led the expedition in person. It proved a disastrous failure, and on the return of the shattered remnants (1171) a great constitutional reform seemed necessary. The Venetians resolved to create a deliberative assembly, which should act with greater caution than the *concione*, which had just landed the state in a ruinous campaign. Forty members were elected in each of the six divisions of the city, giving a body of 480 members, who served for one year and on retiring named two deputies for each *sestiere* to nominate the council for the succeeding year. This was the germ of the great council, the Maggior Consiglio, which was rendered strictly oligarchic in 1296. As the duties of this council were to appoint all officers of state, including the doge, it is clear that by its creation the aristocracy had considerably curtailed the powers of the people, who had hitherto elected the doge in general assembly; and at the creation of Michiel's successor, Sebastiano Ziani (1172), the new doge was presented to the people merely for confirmation, not for election. The assembly protested, but was appeased by the empty formula, "This is your doge an it please you." Moreover, still further to limit the power of the doge, the number of ducal councillors was raised from two to six. In 1198, on the election of Enrico Dandolo, the aristocracy carried their policy one step farther, and by the *promissione ducale*, or coronation oath, which every doge was required to swear, they acquired a powerful weapon for the suppression of all that remained of ancient ducal authority. The *promissione ducale* was binding on the doge and his family, and could be, and frequently was, altered at each new election, a commission, *Inquisitori sopra il doge defunto*, being appointed to scrutinize the actions of the deceased doge and to add to the new oath whatever provisions they thought necessary to reduce the dogeship to the position of a mere figurehead in the state.

In spite of the check to their trade received from the emperor Manuel in 1171, Venetian commerce continued to flourish, the Venetian fleet to grow and the Venetians to amass wealth. When the Fourth Crusade was proclaimed at Soissons, it was to Venice that the leaders applied for transport, and she agreed to furnish transport for 4500 horses, 9000 knights, 20,000 foot, and provisions for one year: the price was 85,000 silver marks of Cologne and half of all conquests. But Zara and Dalmatia had revolted from Venice in 1166 and were as yet unsubdued. Venetian supremacy in the Adriatic had been temporarily shaken. The 85,000 marks, the price of transport, were not forthcoming, and the Venetians declined to sail till they were paid. The doge Dandolo now saw an opportunity to benefit Venice. He offered to postpone the receipt of the money if the Crusaders would reduce Zara and Dalmatia for the republic. These terms were accepted. Zara was recovered, and while still at Zara the leaders of the Crusade, supported by Dandolo, resolved for their own private purposes to attack Constantinople, instead of making for the Holy Land. Boniface, marquis of Monferrat, desired to make good the claim to Salonica, and the Venetians doubtless wished to upset the Greek empire, which had recently shown itself so friendly to their rivals the Genoese. Constantinople fell (1204), thanks chiefly to the ability of the Venetians under Dandolo. The city was sacked, and a Latin empire, with Baldwin of Flanders as emperor, was established at Constantinople (see ROMAN EMPIRE, LATER).

In the partition of the spoils Venice claimed and received, in her own phrase, "a half and a quarter of the Roman empire." To her fell the Cyclades, the Sporades, the islands and the eastern shores of the Adriatic, the shores of the Propontis and the Euxine, and the littoral of Thessaly, and she bought Crete from the marquis of Monferrat. The accession of territory was not only vast, it was of the highest importance to Venetian commerce. She now commanded the Adriatic, the Ionian islands, the archipelago, the Sea of Marmora and the Black Sea, the trade route between Constantinople and western Europe, and she had already established herself in the seaports of Syria, and thus held the trade route between Asia Minor and Europe. She was raised at once to the position of a European power. In order to hold these possessions, she borrowed from the Franks the feudal system, and granted fiefs in the Greek islands to her more powerful families, on condition that they held the trade route open for her. The expansion of commerce which resulted from the Fourth Crusade soon made itself evident in the city by a rapid development in its architecture and by a decided strengthening of the commercial aristocracy, which eventually led to the great constitutional reform—the closing of the Maggior Consiglio in 1296, whereby Venice became a rigid oligarchy. Externally this rapid success awoke the implacable hatred of Genoa, and led to the long and exhausting series of Genoese wars which ended at Chioggia in 1380.

The closing of the great council was, no doubt, mainly due to the slowly formed resolution on the part of the great commercial families to secure a monopoly in the Levant trade which the Fourth Crusade had placed definitely in their hands. The theory of the government, a theory expressed throughout the whole commercial career of the republic, the theory which made Venice a rigidly protective state, was that the Levant trade belonged solely to Venice and her citizens. No one but a Venetian citizen was permitted to share in the profits of that trade. But the population of Venice was growing rapidly, and citizenship was as yet undefined. To secure for themselves the command of trade the leading commercial families resolved to erect themselves into a close gild, which should have in its hands the sole direction of the business concern, the exploitation of the East. This policy took definite shape in 1297, when the Doge Pietro Gradenigo proposed and carried the following measure: the supreme court, the Quarantia, was called upon to ballot, one by one, the names of all who for the last four years had held a seat in the great council created in 1171. Those who received twelve favourable votes became members of the great council. A commission of three was appointed to submit further names for ballot. The three commissioners at once laid down a rule—which contains the essence of the act—that only those who could prove that a paternal ancestor had sat in the great council should be eligible for election. This measure divided the community into three great categories: (1) those who had never sat in the council themselves and whose ancestors had never sat; these were of course the vast majority of the population, and they were excluded for ever from the great council: (2) those whose paternal ancestors had sat in the council; these were eligible and were gradually admitted to a seat, their sons becoming eligible on majority: (3) those who were of the council at the passing of this act or had sat during the four preceding years; their sons likewise became eligible on attaining majority. As all offices were filled by the great council, exclusion meant political disfranchisement. A close caste was created which very seldom and very reluctantly admitted new members to its body. The Heralds' College, the *avvogadori di comun*, in order to ensure purity of blood, were ordered to open a register of all marriages and births among members of the newly created caste, and these registers formed the basis of the famous *Libro d'oro*.

The closing of the great council and the creation of the patrician caste brought about a revolution among those who suffered disfranchisement. In the year 1300 the people, led by Marin Bocconio, attempted to force their way into the great council and to reclaim their rights. The doors were opened, the ringleaders were admitted and immediately seized and hanged. Ten years later a more serious revolution, the only revolution that seriously shook the state, broke out and was also crushed. This conspiracy was championed by Bajamonte Tiepolo, and seems to have been an expression of patrician protest against the *serrata*, just as Bocconio's revolt had represented popular indignation. Tiepolo, followed by members of the Quirini family and many nobles with their followers, attempted to seize the Piazza on the 15th of June 1310. They were met by the Doge Pietro Gradenigo and crushed. Quirini was killed, and Tiepolo and his followers fled.

The chief importance of the Tiepoline conspiracy lies in the fact that it resulted in the establishment of the Council of Ten. Erected first as a temporary committee of public safety to hunt down the remnant of the conspirators and to keep a vigilant watch on Tiepolo's movements, it was finally made permanent in 1335. The secrecy of its deliberations and the rapidity with which it could act made it a useful adjunct to the constitution, and it gradually absorbed many of the more important functions of the state.

With the creation of the Council of Ten the main lines of the Venetian constitution were completed. At the basis of the pyramid we get the great council, the elective body composed of all who enjoyed the suffrage, *i.e.* of the patrician caste. Above the great council came the senate, the deliberative and legislative body *par excellence*. To the senate belonged all questions relating to foreign affairs, finance, commerce, peace and war. Parallel with the senate, but extraneous to the main lines of the constitution, came the Council of Ten. As a committee of public safety it dealt with all cases of conspiracy; for example, it tried the Doge Marino Falier and the General Carmagnola; on the same ground all cases affecting public morals came within its extensive criminal jurisdiction. In the region of foreign affairs it was in communication with envoys abroad, and its orders would override those of the senate. It also had its own departments of finance and war. Above the senate and the Ten came the *Collegio* or cabinet, the administrative branch of the constitution. All affairs of state passed through its hands. It was the initiatory body; and it lay with the *Collegio* to send matters for deliberation either before the senate or before the Ten. At the apex of the pyramid came the doge and his council, the point of highest honour and least weight in the constitution.

To turn now to the external events which followed on the Fourth Crusade. These events are chiefly concerned with the long struggle with Genoa over the possession of the Levant and Black Sea trade. By the establishment of the Latin empire Venice had gained a preponderance. But it was impossible that the rival Venetian and Genoese merchants, dwelling at close quarters in the Levant cities, should not come to blows. They fell out at Acre in 1253. The first Genoese war began and ended in 1258 by the complete defeat of Genoa. But in 1261 the Greeks, supported by the Genoese, took advantage of the absence of the Venetian fleet from Constantinople to seize the city and to restore the Greek empire in the person of Michael VIII. Palaeologus. The balance turned against Venice again. The Genoese were established in the spacious quarter of Galata and threatened to absorb the trade of the Levant. To recover her position Venice went to war again, and in 1264 destroyed the Genoese fleet off Trepani, in Sicilian waters. This victory was decisive at Constantinople, where the emperor abandoned the defeated Genoese and restored Venice to her former position. The appearance of the Ottoman Turk and the final collapse of the Latin empire in Syria brought about the next campaign between the rival maritime powers. Tripoli (1289) and Acre (1291) fell to the Mussulman, and the Venetian title to her trading privileges, her diplomas from the Latin empire, disappeared. To the scandal of Christendom, Venice at once entered into treaty with the new masters of Syria and obtained a confirmation of her ancient trading rights. Genoa replied by attempting to close the Dardanelles. Venice made this action a *casus belli.* The Genoese won a victory in the gulf of Alexandretta (1294); but on the other hand the Venetians under Ruggiero Morosini forced the Dardanelles and sacked the Genoese quarter of Galata. The decisive engagement, however, of this campaign was fought at Curzola (1299) in the Adriatic, when Venice suffered a crushing defeat. A peace, honourable to both parties, was brought about by Matteo Visconti, lord of Milan, in that same year. But the quarrel between the republics, both fighting for trade supremacy—that is to say, for their lives—could not come to an end till one or other was thoroughly crushed. The fur trade of the Black Sea furnished the pretext for the next war (1353–54), which ended in the crushing defeat of Venice at Sapienza, and the loss of her entire fleet. But though Venice herself seemed to lie open to the Genoese, they took no advantage of their victory; they were probably too exhausted. The lord of Milan again arranged a peace (1355).

We have now reached the last phase of the struggle for maritime supremacy. Under pressure from Venice the emperor John V. Palaeologus granted possession of the island of Tenedos to the republic. The island commanded the entrance to the Dardanelles. Genoa determined to oppose the concession, and war broke out. The Genoese Admiral Luciano Doria sailed into the Adriatic, attacked and defeated Vettor Pisani at Pola in Istria, and again Venice and the lagoons lay at the mercy of the enemy. Doria resolved to blockade and starve Venice to surrender. He was master of the sea, and the flow of provisions from the mainland was cut off by Genoa's ally, Francesco I. Carrara, lord of Padua. Doria seized Chioggia as a base of operations and drew his fleet inside the lagoons. The situation was extremely critical for Venice, but she rose to the occasion. Vettor Pisani was placed in command, and by a stroke of naval genius he grasped the weakness of Doria's position. Sailing to Chioggia he blocked the channel leading from the lagoon to the sea, and Doria was caught in a trap. Pisani stationed himself outside the Lido, on the open sea, to intercept relief should any appear, and Doria, instead of blockading Venice, was himself blockaded in Chioggia. For many months the siege went on; but Pisani gradually assumed the offensive as Genoese spirits and food ran low. Finally, in June 1380 the flower of the Genoese fleet surrendered at discretion. Genoa never recovered from the blow, and Venice remained undisputed mistress of the Mediterranean and the Levant trade.

The defeat of Genoa and the establishment of Venetian supremacy in the Mediterranean brought the state to a further step in its development. The undisputed mastery of the eastern trade increased its bulk in Venice. But as the city became the recognized mart for exchange of goods between east and west, the freedom of the western outlet assumed the aspect of a paramount question. It was useless for Venice to accumulate eastern merchandise if she could not freely pass it on to the west. If the various states on the immediate mainland could levy taxes on Venetian goods in transit, the Venetian merchant would inevitably suffer in profits. The geographical position of Venice and her commercial policy alike compelled her to attempt to secure the command of the rivers and roads of the mainland, at least up to the mountains, that is to say, of the north-western outlet, just as she had obtained command of the south-eastern inlet. She was compelled to turn her attention, though reluctantly, to the mainland of Italy. Another consideration drove her in the same direction. During the long wars with Genoa, after the defeats of Curzola, Sapienza, Pola, above all during the crisis of the war of Chioggia, it had been brought home to the Venetians that, as they owned no meat or corn-producing territory, a crushing defeat at sea and a blockade on the mainland exposed them to the grave danger of being starved into surrender. Both these pressing necessities, for a free outlet for merchandise and for a food-supplying area, drove Venice on to the mainland, and compelled her to initiate a policy which eventually landed her in the disastrous wars of Cambrai. The period with which we are now dealing is the epoch of the despots, the *signori*, and in pursuit of expansion on the mainland Venice was brought into collision first with the Scaligeri of Verona, then with the Carraresi of Padua, and finally with the Visconti of Milan. Hitherto Venice had enjoyed the advantages of isolation; the lagoons were virtually impregnable; she had no land frontier to defend. But when she touched the mainland she at once became possessed of a frontier which could be attacked, and found herself compelled either to expand in self-defence or to lose the territory she had acquired.

Venice had already established a tentative hold on the immediate mainland as early as 1339. She was forced into war by Mastino della Scala, lord of Padua, Vicenza, Treviso, Feltre and Belluno, as well as of Verona, who imposed a duty on the transport of Venetian goods. A league against the Scala domination was formed, and the result was the fall of the family. Venice took possession of Padua, but in the terms of the league she at once conferred the lordship on the Carraresi, retaining Treviso and Bassano for herself. But it is not till we come to the opening of the next century that Venice definitely acquired land possessions and found herself committed to all the difficulties and intricacies of Italian mainland politics. On the death of Gian Galeazzo Visconti in 1402, his large possessions broke up. His neighbours and his generals seized what was nearest to hand. Francesco II. Carrara, lord of Padua, attempted to seize Vicenza and Verona. But Venice had been made to suffer at the hands of Carrara, who had levied heavy dues on transit, and moreover during the Chioggian War had helped the Genoese and cut off the food supply from the mainland. She was therefore forced in self-defence to crush the family of Carrara and to make herself permanently mistress of the immediate mainland. Accordingly when Gian Galeazzo's widow applied to the republic for help against Carrara it was readily granted, and, after some years of fighting, the possessions of the Carraresi, Padua, Treviso, Bassano, commanding the Val Sugana route, as well as Vicenza and Verona, passed definitely under Venetian rule. This expansion of mainland territory was followed in 1420 by the acquisition of Friuli after a successful war with the emperor Sigismund, thus bringing the possessions of the republic up to the Carnic and Julian Alps, their natural frontier on the north-east.

Venice was soon made to feel the consequences of having become a mainland power, the difficulties entailed by holding possessions which others coveted, and the weakness of a land frontier. To the west the new duke of Milan, Filippo Maria Visconti, was steadily piecing together the fragments of his father's shattered duchy. He was determined to recover Verona and Vicenza from Venice, and intended, as his father had done, to make himself master of all north Italy. The conflict between Venice and Milan led to three wars in 1426, 1427 and 1429. Venice was successful on the whole. She established her hold permanently on Verona and Vicenza, and acquired besides both Brescia and Bergamo; and later she occupied Crema. The war of Ferrara and the peace of Bagnolo (1484) gave her Rovigo and the Polesine. This, with the exception of a brief tenure of Cremona (1499–1512), formed her permanent territory down to the fall of the republic. Her frontiers now ran from the seacoast near Monfalcone, following the line of the Carnic and Julian and Raetian Alps to the Adda, down the course of that river till it joins the Po, and thence along the line of the Po back to the sea. But long and exhausting wars were entailed upon her for the maintenance of her hold. The rapid formation of this land empire, and the obvious intention to expand, called the attention not only of Italy but of Europe to this power which seemed destined to become supreme in north Italy, and eventually led to the league of Cambrai for the dismemberment of Venice. Contemporaneously other events were menacing the ascendancy and exhausting the treasury of the republic. In 1453 Constantinople fell to the Ottoman Turks, and although Venice entered at once into treaty with the new power and desired to trade with it, not to fight with it, yet it was impossible that her possessions in the Levant and the archipelago should not eventually bring her into collision with the expanding energy of the Mussulman. Europe persistently refused to assist the republic to preserve a trade in which she had established a rigid monopoly, and Venice was left to fight the Turk single-handed. The first Turkish war lasted from 1464 to 1479, and ended in the loss of Negropont and several places in the Morea, and the payment by Venice of an annual tribute for trading rights. She was consoled, however, by the acquisition of Cyprus, which came into her possession (1488) on the extinction of the dynasty of Lusignan with the death of James II. and his son James III., Caterina Cornaro, James II.'s widow, ceding the kingdom of Cyprus to Venice, since she could not hope to maintain it unaided against the Turks. The acquisition of Cyprus marks the extreme limit of Venetian expansion in the Levant; from this date onward there is little to record save the gradual loss of her maritime possessions.

Exhausting as the Turkish wars were to the Venetian treasury, her trade was still so flourishing that she might have survived the strain had not the discovery of the Cape route to the Indies cut the tap-root of her commercial prosperity by diverting the stream of traffic from the Mediterranean to the Atlantic. When Diaz rounded the Cape in 1486 a fatal blow was struck at Venetian commercial supremacy. The discovery of the Cape route saved the breaking of bulk between India and Europe, and saved the dues exacted by the masters of Syria and Egypt. Trade passed into the hands of the Portuguese, the Dutch and the English. Venice lost her monopoly of oriental traffic.

To complete her misfortunes, the European powers, the church and the small states of Italy, partly from jealous greed of her possessions, partly on the plea of her treason to Christendom in making terms with Islam, partly from fear of her expansion in north Italy, coalesced at Cambrai in 1508 for the partition of Venetian possessions. The war proved disastrous for Venice. The victory of Agnadello (1510) gave the allies the complete command of Venetian territory down to the shores of the lagoon. But the mutual jealousy of the allies saved her. The pope, having recovered the Romagna and secured the objects for which he had joined the league, was unwilling to see all north Italy in the hands of foreigners, and quitted the union. The emperor Maximilian failed to make good his hold on Padua, and was jealous of the French. The league broke up, and the mainland cities of the Veneto returned of their own accord to their allegiance to St Mark. But the republic never recovered from the blow, coming as it did on the top of the Turkish wars and the loss of her trade by the discovery of the Cape route. She ceased to be a great power, and was henceforth entirely concerned in the effort to preserve her remaining possessions and her very independence. The settlement of the peninsula by Charles V.'s coronation at Bologna in 1530 secured the preponderance to Spain, and the combination of Spain and the church dominated the politics of Italy. Dread of the Turks and dread of Spain were the two terrors which haunted Venice till the republic fell. That she retained her independence so long was due to a double accident: the impregnability of the lagoons and the jealousies of the great powers.

But the decline was a slow process. Venice still possessed considerable wealth and extensive possessions. Between 1499 and 1716 she went to war four times with the Turks, emerging from each campaign with some further loss of maritime territory. The fourth Turkish war (1570–1573) was signalized by the glorious victory of Lepanto (1571), due chiefly to the prowess of the Venetians under their doge Sebastian Venier. But her allies failed to support her. They reaped no fruits from the victory, and Cyprus was taken from her after the heroic defence of Famagusta by Bragadino, who was flayed alive, and his skin, stuffed with straw, borne in triumph to Constantinople. The fifth Turkish war (1645–1668) entailed the loss of Crete; and though Morosini reconquered the Morea for a brief space in 1685, that province was finally lost to Venice in 1716.

So far as European politics are concerned, the latter years of the republic are made memorable by one important event: the resistance which Venice, under the guidance of Fra Paolo Sarpi, offered to the growing claims of the Curia Romana, advanced by Pope Paul V. Venice was placed under interdict (1606), but she asserted the rights of temporal sovereigns with a courage which was successful and won for her the esteem and approval of most European sovereigns.

But the chief glory of her declining years was undoubtedly her splendid art. Giorgione, Titian, Sansovino, Tintoret, Paolo Veronese and Palladio all lived and worked after the disastrous wars of the league of Cambrai. The chief characteristic of Venice during these years is that she became the great pleasure-city of Europe. The end of the republic came when the French Revolution burst over Europe. Napoleon was determined to destroy the oligarchical government, and seized the pretext that Venice was hostile to him and a menace to his line of retreat while engaged in his Austrian campaign of 1797. The peace of Leoben left Venice without an ally. The government resolved to offer no resistance to the conqueror, and the doge Lodovico Manin abdicated on the 12th of May 1797. On the 17th of October Napoleon handed Venice over to Austria by the peace of Campo Formio, and between 1798 and 1814 she passed from France to Austria and Austria to France till the coalition of that latter year assigned her definitely to Austria. In 1848 a revolution broke out and a provisional republican government under Daniele Manin (*q.v.*) maintained itself for a brief space. In 1866 the defeat of Austria by the Prussians led to the incorporation of Venice in United Italy.

VENISON (pronounced *venzon*), originally a word meaning a beast of any kind killed in the chase, but now only applied to the flesh of the deer prepared for eating. The O. Fr. *veneisun*, *venoison*, &c., mod. *venaison*, meant the flesh of the deer or boar, the principal beasts of the chase (Lat. *venatio*, hunting).

VENLO, a frontier town in the province of Limburg, Holland, on the right bank of the Maas, and a junction station 43 m. by rail N.N.E. of Maastricht. Pop. 15,000. It is joined by a bridge over the Maas, with the opposite village of Blerik. Venlo, with narrow streets irregularly built, is not of the ordinary Dutch type in architectural style. The picturesque town hall (1595), the only building of special interest, contains some interesting paintings by Hubert Goltzius (1526–1583). The church dates from 1304. There is a college for the higher education of Roman Catholic priests. The leading industries are distilling, brewing, tanning, spinning, needlemaking and tobacco manufacture. There is also a considerable trade by river with Rotterdam.

VENN, HENRY (1725–1797), English evangelical divine, was born at Barnes, Surrey, and educated at Cambridge. He took orders in 1747, and was elected fellow of Queens' College, Cambridge, in 1749. After holding a curacy at Barton, Cambridgeshire, he became curate of St Matthew, Friday Street, London, and of West Horsley, Surrey, in 1750, and then of Clapham in 1754. In the preceding year he was chosen lecturer of St Swithin's, London Stone. He was vicar of Huddersfield from 1759 to 1771, when he exchanged to the living of Yelling, Huntingdonshire. Besides being a leader of the evangelical revival, he was well known as the author of *The Compleat Duty of Man* (London, 1763), a work in which he intended to supplement the teaching embodied in the anonymous *Whole Duty of Man*. His son, John Venn (1759–1813), was one of the founders of the Church Missionary Society, and his grandson, Henry Venn (1796–1873), was honorary secretary of that society from 1841 to 1873.

VENOSA (anc. *Venusia, q.v.*), a town and bishop's see of the Basilicata in the province of Potenza, Italy, on the eastern side of Mount Vulture, 52 m. by rail S.S.E. of Foggia, 1345 ft. above sea-level. Pop. (1901) 8503. The castle was built in 1470 by Pirro di Balzo, and contains four stables each for fifty horses. Many fragments of Roman workmanship are built into the walls of the cathedral, which is due to him also. The abbey church of SS. Trinità is historically interesting; it was consecrated in 1059 by Pope Nicholas II. and passed into the hands of the Knights of St John in the time of Boniface VIII. (1295–1303). In the central aisle is the tomb of Alberada, the first wife of Robert Guiscard and mother of Bohemund. An inscription on the wall commemorates the great Norman brothers William Iron Arm (d. 1046), Brogo (murdered at Venosa in 1051), Humfrey (d. 1057) and Robert Guiscard (d. at Corfu in 1085). The bones of these brothers rest together in a simple stone sarcophagus opposite the tomb of Alberada. The church also contains some 14th-century frescoes. Behind it is a larger church, which was begun for the Benedictines about 1150, from the designs of a French architect, in imitation of the Cluniac church at Paray-le-Monial, but never carried beyond the spring of the vaulting. The ancient amphitheatre adjacent furnished the materials for its walls.

VENTILATION (Lat. *ventilare*, from *ventus*, wind), the process and practice of keeping an enclosed place supplied with proper air for breathing; and so, by analogy, a term used for exposing any subject to the winds of public criticism. The air which we breathe consists chiefly of two gases, oxygen and nitrogen, with certain small proportions of other gases, such as carbonic acid (carbon dioxide), ozone and argon. Oxygen, which is the active and important constituent, and on which life and combustion depend, forms about one-fifth of the whole, while nitrogen, which is inert and acts as a diluent, forms nearly four-fifths. Of this mixture each adult person breathes some 2600 gallons or 425 cub. ft. in twenty-four hours. In air that has passed through the lungs the proportion of oxygen is reduced and that of carbon dioxide increased. Of the various impurities that are found in the air of inhabited rooms, carbonic acid gas forms the best practical index of the efficiency of the ventilation. The open air of London and other large inland towns contains about four parts by volume of the gas in 10,000 of air. In the country, and in towns near the sea, two to three and a half parts in 10,000 is a more usual proportion. Authorities on ventilation usually take four parts in 10,000 as the standard for pure air, and use the excess over that quantity in estimating the adequacy of the air supply. But they differ as to the proportion to which the carbonic acid may be allowed to rise under a good system of ventilation. It is generally admitted that the air in which people dwell and sleep should not under any circumstances be allowed to contain more than ten parts in 10,000. This has been accepted as the permissible proportion by Carnelley, Haldane and Anderson, after an extensive examination of the air of middle and lower class dwellings.

Standard of purity.

The rate at which an adult expires carbonic acid varies widely with his condition of repose, being least in sleep, greater in waking rest, and very much greater in violent exercise. As a basis on which to calculate the air necessary for proper ventilation we may take the production of carbonic acid by an adult as 0·6 cub. ft. per hour. Hence he will produce per hour, in 6000 cub. ft. of air, a pollution amounting to one part of carbonic acid in 10,000 of air. If the excess of carbonic acid were to be kept down to this figure (1 in 10,000), it would be necessary to supply 6000 cub. ft. of fresh air per hour; if the permissible excess be two parts in 10,000 half this supply of fresh air will suffice; and so on. We therefore have the following relation between (1) the quantity of air supplied per person per hour, (2) the excess of carbonic acid which results, and (3) the total quantity of carbonic acid present, on the assumption that the fresh air that is admitted contains four parts by volume in 10,000:—

Rate of consumption of air.

Air supplied per Adult per Hour.	Carbonic Acid (Parts by Volume in 10,000).	
Cubic Feet.	Excess due to Respiration.	Total Quantity.
1000	6	10
1200	5	9
1500	4	8
2000	3	7
3000	2	6

Some investigators have maintained that, in addition to an increased proportion of carbonic acid, air which has passed through the lungs contains a special poison. This view, however, is not accepted by others; J. S. Haldane and Lorrain Smith, for instance, conclude "that the immediate dangers from breathing air highly vitiated by respiration arise entirely from the excess of carbonic acid and deficiency of oxygen" (*Journ. Path. and Bact.* 1892, 1, 175). Carbonic acid, however, is not the only agent that has to be reckoned with in badly ventilated rooms, for the unpleasant effects they produce may also be due to increase of moisture and temperature and to the odours that arise from lack of cleanliness. Again, though there may be no unduly large proportion of carbonic acid present, the air of an apartment may be exceedingly impure when the criterion is the number of micro-organisms it contains. This also may be greatly reduced by efficient ventilation. Comparisons carried out by Carnelley, Haldane and Anderson (*Phil. Trans.*, 1887, 178 B, 61) between schools known to be well ventilated (by mechanical means) and schools ventilated at haphazard or not ventilated at all showed that the average number of micro-organisms was 17 per litre in the former, and in the others 152. Results of great interest were obtained by the experiment of stopping the mechanical ventilators for a few hours or days. Tested by the proportion of carbonic acid, the air of course became very bad; tested by the number of micro-organisms, it remained comparatively pure, the number being, in fact, scarcely greater than when ventilation was going on, and far less than the average in "naturally ventilated" schools. This proves in a striking way the advantage of systematic ventilation.

In the ventilation of buildings four main points have to be considered: (1) the area of floor to be provided for each person; (2) the cubic capacity of the room required for each occupant; (3) the allowance to be made for the vitiation of the air by gas or oil burners; and (4) the quantity of fresh air which must be brought in and of vitiated air that must be extracted for each individual. The first will depend upon the objects to which the room is devoted, whether a ward of a hospital or a school or a place of public assembly. The purity of the air of a room depends to a great extent on the proportion of its cubic capacity to the number of inmates. The influence of capacity is, however, often overrated. Even when the allowance of space is very liberal, if no fresh air be supplied, the atmosphere of a room quickly falls below the standard of purity specified above; on the other hand, the space per inmate may be almost indefinitely reduced if sufficient means are provided for systematic ventilation. Large rooms are good, chiefly because of their action as reservoirs of air in those cases (too common in practice) where no sufficient provision is made for continuous ventilation, and where the air is changed mainly by intermittent ventilation, such as occurs when doors or windows are opened. With regard to the third point, in buildings lighted by gas or oil the calculations for the supply of fresh and the extraction of foul air must include an allowance for the vitiation of air by the products of combustion. The rate at which this takes place may be roughly estimated in the case of gas by treating each cubic foot of gas burnt per hour as equal

Ventilation of buildings.

to one person. Thus an ordinary burner giving a light of about twenty candles and burning 4 cub. ft. of gas per hour vitiates the air as much as four persons, and an incandescent burner as much as one and a half persons. A small reading-lamp burning oil uses the air of four men; a large central table lamp uses as much air as seven men.

As to the fourth point there is great diversity of opinion. To preserve the lowest standard of purity tolerated by sanitarians, ventilation must go on at the rate per person of 1000 cub. ft. per hour, and 3000 cub. ft. per hour are required to preserve the higher standard on which some authorities insist. E. A. Parkes advised a supply of 2000 cub. ft. of air per hour for persons in health and 3000 or 4000 cub. ft. for sick persons. In the case of a public assembly hall no great harm will occur to an audience occupying the room for a comparatively short time if 30 cub. ft. of air per minute are provided for each person. The United States book on school architecture gives a practical application to its remarks on this subject as follows:—

The amount of fresh air which is allowed to hospital patients is about 2500 cub. ft. each per hour. Criminals in French prisons have to content themselves with 1500 cub. ft. per hour. Assuming that we care two-thirds as much for the health of our children as we do for that of our thieves and murderers, we will make them an allowance of 1000 cub. ft. each per hour, or about 16 cub. ft. per minute. Forty-eight children will then need an hourly supply of 48,000 cub. ft. Definite provision must therefore be made for withdrawing this quantity of foul air. No matter how many inlets there may be, the fresh air will only enter as fast as the foul escapes, and this can only find an outlet through ducts intended for that purpose, porous walls and crevices serving in cool weather only for inward flow. What, then, must be the size of the shaft to exhaust 48,000 ft. per hour? In a shaft 20 ft. high, vertical and smooth inside, with a difference in temperature of 20°, the velocity will be about $2\frac{1}{2}$ ft. per second, or 9000 ft. per hour; that is, it will carry off 9000 cub. ft. of air per hour for every square foot of its sectional area. To convey 48,000 cub. ft., it must have a sectional area of $5\frac{1}{3}$ sq. ft.

A general idea of the floor area, cubic space and fresh air supply per inmate allowed by law or by custom in certain cases is given in the table below:—

Class of Building.	Floor Area in Feet per Person.	Cubic Capacity in Feet per Person.[1]	Cubic Feet of Fresh Air supplied and Foul Air extracted per Person.
Schools	9 to 10	200	1,800
Barracks	70	720	1,800
Prisons	90	800	1,800
Concert halls and theatres	9	108	2,000
Billiard and smoke-rooms	..	..	2,000
Hospitals	120	1,440	2,000 to 3,000
Public libraries	20	2,400	2,500
Turkish baths	70	800	5,000
Workshops	120	1,440	5,000
Cowsheds, per cow	90	1,100	10,000
Stables; per horse	120	1,600	12,000

[1] In calculating the cubic capacity per person the height should not be measured beyond 12 ft. above the floor.

The supply of fresh air indicated in the table should not be regarded as entirely satisfactory, for the standard of purity suggested is low, and ought to be exceeded, but it might deter many from moving in the matter if a proper and higher standard were to be laid down at first.

One of the most important points is the proper warming of the fresh air introduced into buildings, for unless that be done, when a cold day occurs all the ventilating arrangements will probably be closed. The fact should not be lost sight of that the air in a room may on the one hand be quite cold and yet very foul, and on the other, warm and yet perfectly fresh. To avoid draught the air should enter through a large number of small orifices, so that the currents may be thoroughly diffused. This is done by gratings. The friction of their bars, however, seriously diminishes their capacity for passing air, and careful experiments show conclusively that very ample grating area is required to deliver large volumes. The same remark applies to extracting-flues. Owing to the small size and the roughness of the surface the velocity of the upward current is small, and the quantity of air that passes out is often much less than is requisite.

Means of Ventilation.—In order that the atmosphere of a room should be changed by means of air currents, thereby securing proper ventilation, three things are necessary; (1) an inlet or inlets for the fresh air, (2) an outlet or outlets for the vitiated air, and (3) a motive force to produce and maintain the current. In systems which are distinguished by the general name of *mechanical* or *artificial* ventilation special provision is made for driving the air, by fans, or by furnaces, or by other contrivances to be described more fully below. In what is called *natural* ventilation no special appliance is used to give motive force, but the forces are made use of which are supplied by (1) the wind, (2) the elevated temperature of the room's atmosphere, and (3) the draught of fires used for heating.

Natural Ventilation.—The chief agent in domestic ventilation is the chimney; when a bright fire is burning in an open grate, it rarely happens that any other outlet for foul air from a room need be provided. The column of hot air and burnt gases in the chimney is less heavy, because of its high temperature, than an equal column of air outside; the pressure at the base is therefore less than the pressure at the same level outside. This supplies a motive force compelling air to enter at the bottom through the grate and through the opening over the grate, and causing a current to ascend. The motive force which the chimney supplies has not only to do work on the column of air within the chimney, in setting it in motion and in overcoming frictional resistance to its flow: it has also to set the air entering the room in motion and to overcome frictional resistance at the inlets. From want of proper inlets air has to be dragged in at a high velocity and against much resistance, under the doors, between the window sashes and through many other chinks and crevices. Under these conditions the air enters in small streams or narrow sheets, ill-distributed and moving so fast as to form disagreeable draughts, the pressure in the room is kept so low that an opened door or window lets in a deluge of cold air, and the current up the chimney is much reduced. If the attempt is made to stop draughts by applying sand-bags and listing to the crevices at which air streams in, matters only become worse in other respects; the true remedy of course lies in providing proper inlets. The discharge of air by an ordinary open fire and chimney varies widely, depending on the rate of combustion, the height and section and form of the chimney, and the freedom with which air is entering the room. About 10,000 cub. ft. per hour is probably a fair average, about enough to keep the air fresh for half a dozen persons. Even when no fire is burning the chimney plays an important part in ventilation; the air within an inhabited room being generally warmer than the air outside, it is only necessary that an up-current should be started in order that the chimney should maintain it, and it will usually be found that a current is, in fact, passing up.

Chimney draught.

When a room is occupied for any considerable length of time by more than about half a dozen persons, the chimney outlet should be supplemented by others, which usually take the form of gratings in the ceiling or cornices in communication with flues leading to the open air. These openings should be protected from down-draught by light flap valves of oiled silk or sheet mica.

Other outlets.

With regard to inlets, a first care must be to avoid such currents of cold air as will give the disagreeable and dangerous sensation of draught. At ordinary temperatures a current of outer air to which the body is exposed will be felt as a draught if its velocity exceeds 3, or even 2 ft. per second. The current entering a room may, however, be allowed to move with a speed much greater than this without causing discomfort, provided its direction keeps it from striking directly on the persons of the inmates. To secure this, it should enter, not horizontally nor through gratings on the floor, but vertically through openings high enough to carry the entering stream into the upper atmosphere of the room, where it will mix as completely as possible with warm air before its presence can be felt. A favourite form of inlet is the Sheringham (fig. 1). When opened it forms a wedge-shaped projection into the room, and admits air in an upward stream through the open top. It should be placed at a height of 5 or 6 ft. above the level of the floor. Other inlets are made by using hollow perforated blocks of earthenware, called air-bricks, built into the wall; these are often shaped on the inner

Inlets.

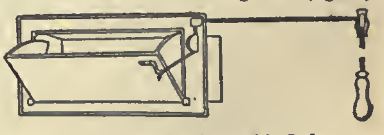

Fig. 1.—Sheringham Air Inlet.

side like an inverted louvre-board or venetian blind, with slots that slope so as to give an upward inclination to the entering stream.

In another and most valuable form of ventilator, the Tobin tube, the fresh air enters vertically upwards. The usual arrangement

Tobin tube.

of Tobin tube (shown in front elevation and section in fig. 2) is a short vertical shaft of metal plate or wood which leads up the wall from the floor level to a height of 5 or 6 ft. Its lower end communicates with the outer air through an air-grating in the wall; from its upper end, which is freely open, the current of fresh air rises in a smooth stream. Various forms of section may be given to the tube: if placed in a corner it will be triangular or segmental; against a flat wall a shallow rectangular form is most usual, or it may be placed in a channel so as to be flush with the face of the wall; a lining of wood forming a dado may even be made to serve as a Tobin tube by setting it out a little way from the wall. The tube is often furnished with a regulating valve, and contrivances may be added for cleansing the entering air. A muslin or canvas bag hung in the tube, or a screen stretched diagonally across it, may be used to filter out dust; the same object is served in some degree by forcing the air, as it enters the tube at the bottom, to pass in close contact with the surface of water in a tray, by means of a deflecting plate. These complications have a double drawback: they require frequent attention to keep them in order, and by putting resistance in the way of the stream they are apt to reduce the efficiency of the ventilation.[1] The air entering by a Tobin tube may be warmed by a coil of hot pipes within the tube or by a small gas-stove (provided, of course, with a flue to discharge outside the products of combustion), or the tube may draw its supply, not directly from the outer atmosphere, but from a hot-air flue. The opening should always be about the level of a man's head, but the tube need not extend down to the floor: all that is essential is that it should have sufficient length to let the air issue in a smooth vertical current without eddies (fig. 3).

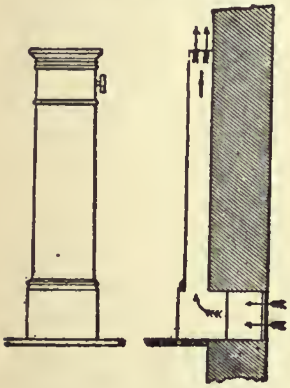

Fig. 2.—Tobin Tube.

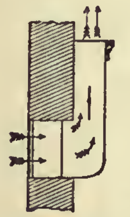

Fig. 3.—Short Tobin Tube.

These inlets are at once so simple and effective that no hesitation need be felt in introducing them freely in the rooms of dwelling-

Ventilation by window and door.

houses. When no special provision is made for them in the walls, the advantage of a current entering vertically may still be in some degree secured by help of certain makeshift contrivances. One of these, suggested by Dr Hinkes Bird, is to open one sash of the window a few inches and fill up the opening by a board; air then enters in a zig-zag course through the space between the meeting rails of the sashes. Still another plan is to have a light frame of wood or metal or glass made to fit in front of the lower sash when the window is opened, forming virtually a Tobin tube in front of the window.

As an example of the systematic ventilation of dwelling-rooms on a large scale, the following particulars may be quoted of arrange-

Arrangements in barracks.

ments that have been successfully used in English barracks. One or more outlet-shafts of wood fitted with flap valves to prevent down-draught are carried from the highest part of the room, discharging some feet above the roof under a louvre. The number and size of these shafts are such as to give about 12 sq. in. of sectional area per head, and the chimney gives about 6 sq. in. more per head. About half the air enters cold through air-bricks or Sheringham valves at a height of about 9 ft. from the floor, and the other half is warmed by passing through flues behind the grate. The inlets taken together give an area of about 11 sq. in. per head. A fairly regular circulation of some 1200 cub. ft. per head per hour is found to take place, and the proportion of carbonic acid ranges from 7 to 10 parts in 10,000.

In the natural ventilation of churches, halls and other large rooms we often find air admitted by gratings in the floor or near it; or the inlets may consist, like Tobin tubes, of upright flues rising to a height of about 6 ft. above the floor, from which the air proceeds in vertical streams. If the air is to be

In public buildings.

warmed before it enters, the supply may be drawn from a chamber warmed by hot-water or steam pipes or by a stove, and the temperature of the room may be regulated by allowing part of the air to come from a hot chamber and part from outside, the two currents mixing in the shaft from which the inlets to the room draw their supply. Outlets usually consist of gratings or plain openings at or near the ceiling, preferably at a considerable distance from points vertically above the inlet tubes. One of the chief difficulties in natural ventilation is to guard them against down-draught through the action of the wind. Numberless forms of cowl have been devised with this object, with the further intention of turning the wind to useful account by making it assist the up-current of foul air. Some of these exhaust cowls are of the revolving class, made to various designs and dimensions and put in rotation by

Exhaust cowls.

the force of the wind. Revolving cowls are liable to fail by sticking, and, generally speaking, fixed cowls are to be preferred. They are designed in many forms, of which Buchan's may be cited as a good example. Fig. 4 shows this ventilator in horizontal section: *aa* is the vertical exhaust flue through which the foul air rises; near the top this expands into a polygonal chamber, *bbbb*, with vertical sides, consisting partly of perforated sheet-metal plates; outside of these are fixed vertical curved guide-plates, *c,c,c,c*; the wind, blowing between these and the polygonal chamber, sucks air from the centre through the perforated sides. The efficient working of an exhaust cowl, however, depends almost entirely upon the favourable conditions of the wind.[2] The two things that supply motive force in automatic or natural ventilation by means of exhaust cowls and similar appliances—the difference of temperature between inner and outer air, and the wind—are so variable that even the best arrangements of inlets and outlets give a somewhat uncertain result. As an example, it is evident that on a hot day with little movement in the air this mode of ventilation would be practically ineffectual. Under other conditions these automatic air-extractors not infrequently become inlets, thus reversing the whole system and pouring cold air on the heads of the inmates of the apartment or hall. To secure a strictly uniform delivery of air, unaffected by changes of season or of weather, it is necessary that the influence of these irregular motive forces be as far as possible minimized, and recourse must consequently be had to some mechanical force as a means of driving the air and securing adequate ventilation of the building.

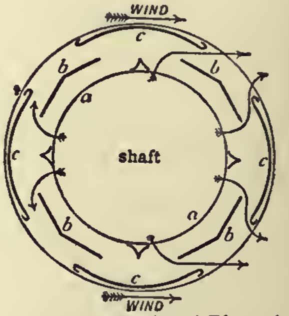

Fig. 4.—Sectional Plan of Buchan's Exhaust Cowl.

Artificial Ventilation.—Buildings may be mechanically ventilated on the vacuum system, the plenum system, or on a system combining the best points of both. In nearly every case of the application to modern buildings of mechanical means of ventilation the combined system in one form or another is adopted. In the vacuum system the motive force is applied at the outlets; the vitiated air is drawn from the rooms, and the pressure of the atmosphere in them is slightly less than the pressure outside. Upon the foul air being withdrawn fresh air finds its way in by means of conveniently placed inlets. In the plenum the motive force is applied at the inlets; fresh air is forced in and drives the vitiated air before it until it escapes at the outlets provided. The pressure within the room is greater than outside. The plenum method has distinct advantages: it makes the air escape instead of coming in as a cold draught at every crevice and casual opening to the outer air; it avoids drawing foul air from sewers and basement; and with it, more easily than with the other, one may guard against the disturbing influence of wind. In the plenum method the air is driven by fans; in the vacuum method suction is produced by fans or by heating the column of air in a long vertical shaft through which the discharge takes place. Water jets and steam jets have also been employed to impel or extract the air. Whatever system of ventilation is adopted, it is most important that windows capable of being widely opened should also be provided to aërate at frequent intervals the whole building, either as a whole or in sections, and they should be so arranged that no corner can be left stagnant or unswept by the purifying current. The Victoria Hospital at Glasgow and the Royal General Hospital at Birmingham are, however, ventilated on the plenum system without the aid of open windows, with what are said to be satisfactory results. In the case of hospitals, it is evident that aëration by means of open windows could not in Great Britain be effected except on warm and sunny

---

[1] When the air is not filtered, and when it has been warmed before entering, the vertical direction of the stream is readily traced by dust, which is deposited on the wall in a nearly upright column, spreading slightly fan-wise as it rises. With cold air the deposit of dust is comparatively slight. The difference is due to the fact, noticed and explained by Mr John Aitken, that air quickly deposits any suspended particles when it is brought into contact with a surface colder than itself, but retains them in suspension if the surface be warmer than the air. Another domestic illustration of the same fact is given by the greater dustiness of walls and furniture in a stove-heated room than in a room heated by an open fire.

[2] For an account of tests of various forms of ventilating cowls, see S. S. Hellyer, *The Plumber and Sanitary Houses.*

days, but in the case of concert halls, theatres and similar buildings, it is possible (and most essential) thoroughly to aërate the building between each occupation.

The extraction of foul air should in most cases be effected at the top of a room or building, so as to utilize the natural tendency of warm air to rise; but at Birmingham and elsewhere the outlets are near the floor, the fresh air being brought in half-way up the walls and directed towards the ceiling. The air inlets should be Tobin tubes or similar devices, placed some 4 or 5 ft. above the floor, and so arranged that the air should be passed in contact with radiators or pipes to warm it before entering. In the case of a building for one of the American legislatures, the warmed fresh air is allowed to enter on the level in front of the desk of each member, so that he secures a proper volume of fresh air for his own use before it is breathed by his neighbour.

Extraction of vitiated air.

The introduction of rapidly revolving, but silent, fans, driven by electricity, is a great advance which places within the reach of the engineer or architect the means for solving the problem of ventilation of buildings, and has been to a large extent responsible for the rapid progress of the art of ventilation. The fan and motor combined extend the advantages of positive mechanical ventilation to all who have access to electric current, with the further benefit that the extreme simplicity of the electric driving of the fans greatly facilitates the control and distribution of ventilating effect. The moderate power required by these fans for a given duty has contributed greatly to their extended use. They should deliver into a chamber of considerable size, so that the velocity of the air may become reduced before it passes into the distributing flues. The question of silence in running, in such places as houses of parliament, law courts, churches and chapels, is of paramount importance, and no fan should be accepted until it is proved by actual working to be noiseless.

Fans.

In some instances revolving pumps of the Root's blower type are used (see BELLOWS AND BLOWING MACHINES). At the Dundee College a battery of five of these blowers, each discharging over 150,000 cub. ft. of air per hour, is driven easily by a gas engine of two horse-power. The air is passed through two filters of coarsely woven fabrics which serve to remove all particles of impurity. The rooms are heated by having coils of Perkins's high-pressure hot-water pipes (see HEATING) in the main distributing flues. The inlets are flat upright tubes extending up the side walls to a height of nearly 6 ft., and open at the top. Outlets are generally provided in the end walls, one group near the ceiling, another a few feet from the foot. They are fitted with doors which allow one or other to be closed; the high-level outlets are used in warm weather, when the fresh air that comes in is comparatively cool; the low-level ones are used in cold weather, when the fresh air, having been heated before it enters, would tend to rise and pass out too directly if the outlets near the ceiling were open. The outlet shafts communicate with a louvred tower or turrets on the roof. Each room receives a volume of air equal to its cubic capacity in about 12 minutes, so that the atmosphere is completely changed five times in an hour. The inlets are proportioned to do this without allowing the velocity with which air enters to exceed 6 ft. per second.

The water-spray ventilator is a mechanical ventilator using a jet of water to impel the air. A nozzle at the top of a circular air-shaft delivers a conical sheet of water, which impinges on the sides of the shaft a little way below and carries down with it a considerable stream of air. This ventilator is used either to force air into rooms or to draw it out; in the former case a small stove is often added to heat the supply.

Water-spray ventilator.

In the early days of mechanical ventilation extraction by a hot-air shaft was a more common mode of ventilating hospitals and other public buildings than now. The heat was applied by a furnace or stove at the bottom of the shaft, or by coils of hot-water or steam pipes. In the lecture theatre of the Paris Conservatoire des Arts A. J. Morin employed this means of extraction, and arranged that the fresh air should enter through the ceiling and the foul air be drawn off through the floor from under the seats; this reversal of the natural direction of the current is of course only possible when a sufficient external motive force is applied.

Extraction by hot-air shaft.

In theatres and similar buildings clusters of gas jets or sunlight burners, fixed at the ceiling level at the base of a metal shaft which is connected with the open air, serve as effective ventilating agents by extracting the foul air which collects in the upper part of the hall.

To ensure the admission of the desired amount of air into a room, and to arrive at the proper allowance of inlets and outlets, it is necessary to ascertain the direction and velocity of the movement of the air through them. The quantity of air passing through a given opening is found by multiplying the area of the opening expressed in square feet by the velocity of the current of air stated in lineal feet per minute, the product being the number of cubic feet passing per minute. Where the air is admitted through gratings only the clear area should be calculated, the amount of solid material being deducted from the gross superficies of the grating. The velocity of the air current may be determined by means of an anemometer (*q.v.*).

The measurement of air.

We may conclude with a short summary of the methods adopted of ventilating a number of typical buildings of various classes of different countries.

The Smallpox Hospital at Bradford consists of two wards, 75 ft. by 15 ft., placed back to back, with a space of about 3 ft. between them enclosed by walls forming a foul-air chamber of the same length as the wards, and reaching to the ceiling. At this level are outlets for the vitiated air—one over each bed. A furnace at the base of a tall shaft withdraws through these outlets the air which passes through the furnace on its way to the outer air. The windows are tightly closed and fresh air enters from a chamber below through gratings in the floor at the foot of each bed.

The New York General Hospital was stated in 1875 to contain 163 beds. In the wards there is one window to each bed, each pier between the windows containing a foul-air extracting flue running from the base of the building and connected in the roof with large trunks leading to an exhaust fan. The heating is by steam coils placed in the basement in such a way that by a valve the cool fresh air can be sent either through or around the heating coil. The warmed fresh air is conveyed through an air-tight iron pipe fitted in each extracting shaft and is admitted to the wards through slits in the window-sills forming a jet directed upward on the principle of Tobin tubes. The outlet openings for the foul air are placed one beneath each bed, with extra outlets for occasional use at the top and base of the external walls. The placing of the fresh-air supply pipes in an inaccessible position inside the foul air ducts cannot be approved for hospital ventilation, as it is quite possible that in time, through the decay of the pipe joints or of the pipes themselves, communication may be established between the fresh and foul air, thus entirely upsetting the system of ventilation.

The City Hospital of Hamburg, containing 130 beds, was opened in 1890. The buildings are one storey high and are heated on the ancient Roman hypocaust principle. Beneath the entire floor run longitudinally a number of brick and concrete flues about 30 in. square, covered on the top with marble tiles, forming the floor of the wards. In these flues are placed the steam heating pipes. Warmed fresh air is admitted through large radiators in the centre of the wards, the vitiated air escaping through openings in the ridge of the roof. Mr H. Percy Adams adopted a similar hypocaust method for warming the chapel and the dining-hall at the King Edward VII. Tuberculosis Sanatorium at Midhurst, Sussex, except that the radiators are omitted from the centre of the rooms and placed in recesses in the side walls.

In the Houses of Parliament at Westminster, which were designed and built for the public business in 1836, considerable attention is devoted to the question of the purification of the air, but the arrangements are lamentably antiquated and ineffectual in their working. The supply of fresh air is drawn by fans from the terrace at the river front, and, after being warmed and moistened or cooled by water-spray or blocks of ice, as the temperature may require, passes through exceedingly tortuous and restricted air passages to the various chambers, where it is admitted through large gratings in the floor, which are covered by porous matting to prevent draughts. The outlets for the vitiated air are in the ceilings of the apartments, and from these the air has to be dragged down to the base of the ventilating shaft in the Victoria tower, where an up-current is maintained by a large furnace.

The French Chamber of Deputies, according to a report made by M. Frélat in 1891, is much overcrowded, the allowance of floor space for each member being only 30 square centimetres. The apparatus is powerful enough to change the air every six minutes, but to avoid draughts it can only be worked slowly. Fresh air is driven down by a fan through openings in the ceiling, and vitiated air removed at the floor, giving a downward system of ventilation.

For the ventilation of the new Sessions House at the corner of Newgate Street and Old Bailey, London, opened in 1907, an elaborate system on the plenum downward principle was installed. The fresh air, drawn in at the basement by powerful fans, passed in turn through purifying screens, on which water was constantly playing, and over steam-heated coils, before entering the distributing trunks; into these sufficient cold air also was admitted to reduce it to the required temperature. Branch ducts conveyed this warmed fresh air to the points of inlet just below the ceiling. The outlets for the vitiated air were placed near the floor level, an electric fan drawing it up and discharging it at the roof. It was claimed that 600 tons of filtered and warmed or cooled fresh air were passed through the building every hour.

In the Capitol at Washington in America the upward system is installed. Fresh air, warmed by coils in the basement, is delivered by means of fans through openings in the floors of the various chambers and galleries, and the extractors are placed in the ceilings. This foul air passes out of the building through louvre ventilators placed on the roof ridge. Some of the vitiated atmosphere, however—that from the corridors and galleries—is drawn by means of a fan to the basement and blown up a lofty shaft.

The Grand Opera House in Vienna is ventilated on a most elaborate and complete system, the arrangements there giving excellent results. The scheme for heating and ventilating this building was designed by D. Böhm. The building measures 397 ft. by 299 ft., and the theatre will hold about 2700 persons. Ventilation is effected by two fans, the lower for propulsion, the upper for extraction. The latter is aided also by the heat produced by the great pendant which has ninety burners. The heating is effected by steam, and the air enters the hall at a temperature of from 63° to 65° F., the points of entrance being at the floor and the risers of the seating. Each gallery and compartment of the theatre, including the stage, has a separate installation of heating apparatus and supply duct so that any one portion may be warmed and ventilated independently of the rest. The velocity of the incoming air is between 1 and 2 ft. per second. The driving fan in the basement sends air into the building at the rate of 1059 cub. ft. per head per hour by means of electricity. The temperature in different parts of the house can be observed in a central control office, and here also are the levers which control the valves regulating the air supply, both hot and cold. During a performance the superintendent of heating and ventilation is on duty in this office and secures to each part of the building its proper supply of fresh air at a proper temperature.

For the ventilation of mines see MINING, and for that of railway tunnels see TUNNEL.

AUTHORITIES.—The following are the principal publications on ventilation: J. S. Billings, *Ventilation and Heating*; Leeds, *Treatise on Ventilation*; Carpenter, *Heating and Ventilating Buildings*.
(J. BT.)

VENTIMIGLIA (Fr. *Vintimille*, anc. *Album Intimilium* or *Albintimilium*), a frontier fortress, seaport and episcopal see of Liguria, Italy, in the province of Porto Maurizio, 94 m. W. by S. of Genoa by rail, and 4 m. from the Franco-Italian frontier, 45 ft. above sea-level. Pop. (1901) 3452 (town); 11,468 (commune). The present Gothic cathedral is built on the ruins of an earlier Lombard church, and this again on a Roman building, possibly a temple. The ruins of the ancient town are situated in the plain of Nervia, 3 m. to the E. of the modern. It was a *municipium* with an extensive territory, and of some importance under the Empire, but was plundered by the partisans of Otho in A.D. 69. Remains of a theatre are visible, and remains of many other buildings have been discovered, among them traces of the ancient city walls, a fine mosaic, found in 1852 but at once destroyed, and a number of tombs to the west of the theatre. The caves of the Balzi Rossi have proved rich in palaeolithic remains of the Quaternary period.

See *Notizie degli Scavi, passim*, especially 1877, 288 (G. Rossi).

VENTNOR, a watering-place in the Isle of Wight, England, 12½ m. S. by W. of Ryde by rail. Pop. of urban district (1901) 5866. It is finely situated in the Undercliff district, at the foot of St Boniface Down, which reaches a height of 787 ft. The town is built on a succession of terraces sloping towards the sea, and from its sheltered situation, equable temperature, and comparatively dry atmosphere is regarded as one of the best resorts in England for consumptive invalids. In the middle of the 19th century it was only a small fishing hamlet, now it extends along the shore for a distance of about 2 m., including Bonchurch to the east. It possesses assembly rooms, a literary and scientific institution, an esplanade, a pier and extensive recreation grounds. The churches of Ventnor are all modern, but that of St Boniface at Bonchurch is a small Norman building, perhaps the oldest in the island. Among the benevolent and charitable institutions are the royal national hospital for consumptives (founded in 1869), the seaside home of the London city mission, the St Catherine's home for consumptives and the convalescent home of the Royal Hants Hospital.

VENTRILOQUISM (Lat. *venter*, belly, and *loqui*, to speak), the art of producing the voice in such a manner that it shall appear to proceed, not from the speaker's own mouth, but from some place altogether distant from him. The art of ventriloquism was formerly supposed to result from a peculiar use of the stomach (whence the name) during the process of inhalation. As a matter of fact, the words are formed in the normal manner, but the breath is allowed to escape very slowly, the tones being muffled by narrowing the glottis and the mouth opened as little as possible, while the tongue is retracted and only its tip moves. Gestures and facial expression are employed at the same time to assist in the deception by stimulating the imagination of the listeners and to distract their attention from the speaker. "Thus," says Huxley, "if the ventriloquist desire to create the belief that a voice issues from the bowels of the earth, he imitates, with great accuracy, the tones of such a half-stifled voice, and suggests the existence of some one uttering it by directing his answers and gestures towards the ground. The gestures and tones are such as would be produced by a given cause; and, no other cause being apparent, the mind of the bystander insensibly judges the suggested cause to exist." Ventriloquism, which is still a recognized form of conjuring entertainment, is of ancient origin. Traces of the art are found in Egyptian and Hebrew archaeology. Eurykles of Athens was the most celebrated of Greek ventriloquists, who were called after him Euryklides, and also *Engastrimanteis* (belly-prophets). It is not impossible that the priests of ancient times were masters of this art, and that to it may be ascribed such miracles as the speaking statues of the Egyptians, the Greek oracles, and the stone in the river Pactolus, the sound of which put robbers to flight. Many uncivilized races of modern times are adepts in ventriloquism, as the Zulus, the Maoris and the Eskimos. It is well known in Hindustan and China, where it is practised by travelling magicians.

See De la Chapelle, *Le Ventriloque, ou l'engastrimythe* (London, 1772); E. Schultz, *Die Kunst des Bauchredens* (Erfurt, 1895); Sievers, *Grundzüge der Phonetic* (Leipzig, 1901); Russel, *Ventriloquism* (London, 1898).

VENUE (derived through the French, from Lat. *venire*, to come), in English law the term denoting the place from which a jury must come for the trial of a case. The word occurs early in constitutional documents, for it was for a long time one of the essentials of trial by jury that the jury should belong to the neighbourhood (*vicinetum, visne*) in which the cause of action arose or the alleged crime was committed (see JURY). This was founded on the idea that the jurors were in the nature of witnesses for or against the character or innocence of the party. The phrase *duodecim legales homines de vicineto*, or its equivalent, is found in the Constitutions of Clarendon (1164), the Assize of the Forest (1184) and in Glanvill.

Civil Matters.—Civil actions came to be classified as local and transitory, the former where the cause of action could only arise in a particular county, such as trespass to land, the latter where it might have arisen in any county, such as debt. In the latter case the plaintiff might lay the venue where he pleased, *i.e.* try the cause in any part of England subject to the power of the court or a judge to change the place of trial. The law on the subject is now only of antiquarian interest, for under the rules of the Supreme Court (Ord. xxxvi. r. 1), "there shall be no local venue for the trial of any action, except where otherwise provided by statute, but in every action in every division the place of trial shall be fixed by the court or a judge." All local venues created by statutes prior to 1875 were superseded by the rules of the Supreme Court and have not been revived by the present rules; and many of such statutes have been expressly or impliedly repealed by the Public Authorities Protection Act 1893. The present practice is to fix the place of trial in the order for directions now made in every civil action in the High Court. The place is selected by reference to the wishes of the parties, the residence of the witnesses, and with a view to reducing the costs of litigation.

Criminal Matters.—Proceedings by indictment or criminal information are not affected by the changes of procedure as to civil actions; and it is necessary to ascertain in the case of each offence the venue, *i.e.* the proper place of trial, which, unless otherwise provided by statute, must be the county or other jurisdiction in which acts constituting the offence have been done. Numerous acts provide for the place of trial of offences committed partly in one county and partly in another, or on the high seas or abroad, and of special offences, such as those under the Post Office, Merchant Shipping, Slave Trade, and Foreign Enlistment Acts. The place of trial may be changed by the king's bench division, where it is probable that a fair trial could not be had in the county of the venue. Until 1825 it was necessary to have as juries in criminal cases jurors from the hundred in which the offence was said to have been committed, and to be very particular to specify the venue as to each act imputed to the accused. This strictness continued to some extent until the passing of the Criminal Procedure Act 1851, which makes it unnecessary to state any venue in the body of an indictment, and no indictment is to be held bad for want of a proper perfect venue. Since this enactment (which applies to Ireland as well as to England) it is sufficient to state the venue in the margin of the indictment in this form, "Middlesex to wit," and it is unnecessary to mention the venue in the body of the indictment or information, though in certain cases such as burglary it is usual, if not essential, to give a "local description."

Scotland.—In Scottish law venue is not used as a technical term, but there are statutory provisions for changing the place of trial in both civil and criminal cases.

United States.—In the United States venue may generally be changed by the courts; but in some states it is provided by their constitutions that provision for change of venue is to be made by the legislature. In other states the passing of local or special laws for change of venue is forbidden. (W. F. C.)

VENUS, an old Roman and Latin goddess, apparently representing beauty and growth in nature, and especially in gardens, where the Roman practical sense would most naturally see these. She had two temples in Rome, one in the grove of Libitina, with whom she was wrongly identified, and the other near the Circus Maximus, both of which had as their dedication day the 19th of August, the festival of the *Vinalia rustica*, a fact which also points in the direction of skilled cultivation as the human work of which she was protectress. But this old Latin deity was in historical times entirely absorbed by the Greek Aphrodite, and assumed the characteristics of a cult of human love, which in her original form she had never possessed. (See APHRODITE.)

VENUS, in astronomy, the second of the major planets in the order of distance from the sun, and moving next within the orbit of the earth. Its symbol is ♀. At inferior conjunction it approaches nearer to the earth than any other major planet, but in that position it is practically invisible. Its apparent motion may be described as an oscillation from one side of the sun to the other, the complete period of which is 1·6 years, and the greatest elongation about 45° on each side of the sun. When east of the latter it appears as the "evening star" in the west after sunset, while near western elongation it is seen as the "morning star" before sunrise. In these aspects it was known to the ancients as Ἕσπερος, Hesperus, and Ἑωσφόρος or Φωσφόρος, Phosphorus. The eccentricity of its orbit is smaller than that of any other planet except Neptune.

Notwithstanding the near approach of Venus to the earth, its situation relative to the sun is unfavourable to the study of its physical constitution. Near inferior conjunction only a narrow crescent of light is visible; and when, as the planet moves away, this crescent becomes broader, the distance of the planet constantly increases. When it appears as a half-moon it is at a distance of more than two-thirds that of the sun, and nearly double the distance of Mars in opposition. The difficulty of reaching any conclusion on the subject of its constitution is heightened by the seeming absence of any well-marked features on the visible part of its brilliant surface. In the telescope it presents much the appearance of burnished silver, without spot or blemish. It is true that observers have from time to time thought they could detect slight variations of shade indicating an axial rotation. As far back as 1667 G. D. Cassini thought he saw a bright spot near the southern horn, observations of which gave a period of about 23 hours. In 1726 Francesco Bianchini (1662–1729), a papal chamberlain, made similar observations from which he inferred a period of more than 24 days. It was shown, however, that the observations of Bianchini could be reconciled with those of Cassini by supposing that, as he observed the planet night after night, it had made one rotation and a little more. J. H. Schroeter also found a revolution of less than 24 hours. But Sir W. Herschel, as in the case of Mercury, was never able to detect any changes from which a period of rotation could be determined. During the years 1888–1890, G. Schiaparelli made an exhaustive study of the whole subject, the results of which were summed up in five brief notes, read to the Lombardian Academy of Sciences during the year 1890. His general conclusion was that Venus always presents the same face to the sun, as the moon does to the earth. The same result has been reached by the observations at the Lowell Observatory. The inference that the axial rotation is at least much slower than that of the earth is strengthened by the measures of different diameters of the planet made while it was in transit across the disk of the sun in 1874 and 1882. These show no measurable ellipticity of the disk, but they are not sufficiently accurate to lead to any more precise conclusion than that just stated. Still, the difficulty and uncertainty attending all observations hitherto made upon the disk are such that no conclusion respecting the time of rotation can be regarded as established. Against the view of Schiaparelli is to be set the great improbability that a body so distant from the sun as Venus could be permanently so acted upon as to keep its axial rotation in precise coincidence with its orbital motion. Only one way seems to be open for settling the question; this is by spectroscopic observations of the displacement of the spectral lines at the two limbs of the planet. Attempts by this method have been made by A. A. Belopolski at Pulkova, and by the astronomers of the Lowell Observatory. It is, however, found that the amount of displacement is so small that it has evaded certain detection up to the present time. Belopolski's measures were decidedly in favour of an axial rotation, while the Lowell results were not.

Rotation of Venus.

Other observations than those we have cited show that Venus is surrounded by an atmosphere so filled with clouds that it is doubtful whether any view of the solid body of the planet can ever be obtained. The first evidence in favour of an atmosphere was found in the fact that, when near inferior conjunction, the visible outline of the thin crescent extended through more than 180°. Most remarkable was an observation by Chester Smith Lyman at New Haven during the conjunction of 1866, when the planet was just without the sun. A thin line of light was supposed to be seen all round the limb of the planet most distant from the sun. But as no such appearance was seen during the approach of the planet to the sun at the transits of 1874 and 1882, when the conditions were much more favourable, it seems likely that such observations are the result of an optical illusion. During the latter of the two transits the phenomena of this class observed were of an unexpected character. Not a trace of the planet could be seen until it began to impinge upon the solar disk. When about half of its diameter had entered upon the sun the outline outside the disk of the sun began to be marked by broken portions of an arc of light. This did not begin at the point A (fig. 1) farthest from the sun, as it should have done if due

Atmosphere of Venus.

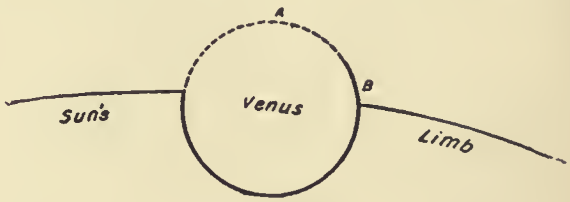

FIG. 1.

wholly to refraction, but immediately at the sun itself, as shown in the cut at the point B. Portions of this arc were formed one by one at various other points of the dotted outline, and when the planet was about three-fourths upon the sun the arc was completed. But there was no strengthening of the line at the middle point, as there should have been if due to refraction. Yet refraction must have played some part in the phenomenon, because otherwise no illumination could have been visible under the circumstances. The most satisfactory explanation seems to be that of H. N. Russell, whose conclusion is that the atmosphere is so permeated with fine particles of vapour up to its outer limit as to be only translucent without being fully transparent. Thus what is seen is the irregular reflection of the light at an extremely small angle from the particles of vapour.

The question whether Venus has a satellite has always interested astronomers. During the 17th and 18th centuries Cassini at Paris and James Short (1710–1768) in England, as well as other observers during the same period, saw an object which had the appearance of a satellite. But as no such object has been seen by the most careful search with the best instruments of recent times, the supposed object must be regarded as what is known to the practical astronomer as a "ghost" produced by refraction from the lenses of the eyepiece, or perhaps of the object-glass, of the telescope.

Supposed satellite.

If the orbit of Venus lay in the plane of the ecliptic, it would be seen to pass over the disk of the sun at every inferior conjunction.

Transits of Venus. But the inclination of the orbit, 3° 36′, is so large that a transit is seen only when the earth and Venus pass a node of the orbit at nearly the same time. The earth passes the line of nodes about the 7th of June and the 7th of December of each year. The date of passage is about a day later in each successive century. Venus passes the node near enough to these dates to be seen against the sun only four times in a period of 243 years. The following list of dates from 1518 to 2012 shows the law of recurrence.

1518 June 2.	1769 June 3.
1526 June 1.	1874 December 9.
1631 December 7.	1882 December 6.
1639 December 4.	2004 June 8.
1761 June 6.	2012 June 6.

The first of these transits actually seen was that of 1639, which was imperfectly observed by Jeremiah Horrox (1619–1641) shortly before sunset. Special interest in them was first excited by Edmund Halley a century later, who showed that the parallax of the sun could be determined by observing transits of Venus from regions of the earth's surface where the displacement by parallax was greatest. Governments, scientific organizations and individuals fitted out expeditions on a very large scale to make the necessary observations upon the four transits which have since occurred. The disappointing character of the results so far as the solar parallax is concerned are stated in the article PARALLAX, SOLAR. It may be said in a general way that the observations, even when made by experienced astronomers, exhibited irregularities and discordances several times greater than one had a right to expect. Other methods of determining the distance of the sun have been so perfected that the results of these transits now count but little. (S. N.)

VENUSIA (mod. *Venosa, q.v.*), an ancient city of Apulia, Italy, on the Via Appia, about 6 m. S. of the river Aufidus (Ofanto), and not far from the boundary of Lucania (hence Horace describes himself as "Lucanus an Apulus anceps, nam Venusinus arat finem sub utrumque colonus"). It was taken by the Romans after the Samnite war of 291 B.C., and became a colony at once, no fewer than 20,000 men being sent there, owing to its military importance. Throughout the Hannibalic wars it remained faithful to Rome, and had a further contingent of colonists sent in 200 B.C. to replace its losses in war. Some coins of Venusia of this period exist. It took part in the Social War, and was recaptured by Quintus Metellus Pius; it then became a *municipium*, but in 43 B.C. its territory was assigned to the veterans of the triumvirs, and it became a colony once more. Horace was born here, the son of a freedman, in 65 B.C. It remained an important place under the Empire as a station on the Via Appia, though Mommsen's description of it (*Corp. Inscr. Lat.* ix. p. 45) as having branch roads to Equus Tuticus and Potentia, and Kiepert's maps annexed to the volume, do not agree with one another. Remains of the ancient city walls and of an amphitheatre still exist, and a number of inscriptions have been found there. Jewish catacombs with inscriptions in Hebrew, Greek and Latin show the importance of the Jewish population here in the 4th and 5th centuries after Christ. (T. As.)

VENUS'S FLY-TRAP (*Dionaea muscipula*), a remarkable insectivorous plant, a native of North and South Carolina, first described in 1768 by the American botanist Ellis, in a letter to Linnaeus, in which he gave a substantially correct account of the structure and functions of its leaves, and even suggested the probability of their carnivorism. Linnaeus declared it the most wonderful of plants (*miraculum naturae*), yet only admitted that it showed an extreme case of sensitiveness, supposing that the insects were only accidentally captured and subsequently allowed to escape. The insectivorous habit of the plant was subsequently fully investigated and described by Charles Darwin in his book on insectivorous plants.

The plant is a small herb with a rosette of radical leaves with broad leaf-like footstalks. Each leaf has two lobes, standing at rather less than a right angle to each other, their edges being produced into spike-like processes (fig. 1). The upper surface of each lobe is covered with minute circular sessile glands, each consisting of from 20 to 30 cells filled with purplish fluid; it bears also three fine-pointed sensitive bristles arranged in a triangle (fig. 3). These contain no fibro-vascular bundles, but present an articulation near their bases, which enables them to bend parallel to the surface of the leaf when the lobes close. When the bristles are touched by an insect the lobes close very sharply upon the hinge-like midrib, the spikes interlock, and the insect is imprisoned (fig. 2). If very minute, and so not worth digesting, it is able to escape between the interlocked spines; more usually, however, it is retained between the lobes, which gradually but firmly compress it, until its form is distinguishable from without. The leaf thus forms itself into a temporary stomach, and the glands, hitherto dry, commence, as soon as excited by the absorption of a trace of nitrogenous matter, to pour out an acid secretion containing a ferment or *enzyme*, similar to that excreted by the leaves of the sundew, which rapidly dissolves the soft parts of the insect. This is produced in such abundance that, when Darwin made a small opening at the base of one lobe of a leaf which had closed over a large crushed fly, the secretion continued to run down the footstalk during the whole time—nine days—during which the plant was kept under observation. The closing of the leaf is due to a redistribution of water in the cells brought about by a change in the protoplasm which follows the stimulation of the sensitive bristles.

FIG. 1.—Leaf of Venus's Fly-Trap (*Dionaea muscipula*), viewed laterally in its expanded state, slightly enlarged. (After Darwin.)

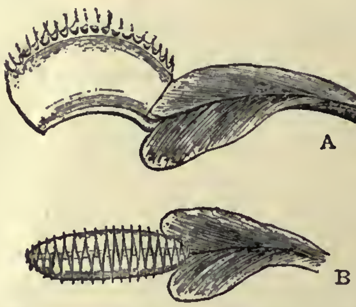

FIG. 2.—Leaf of *D. muscipula* closed over Insect. A, viewed from the side; B, from above.

Though the bristles are exquisitely sensitive to the slightest contact with solid bodies, yet they are far less sensitive than those of the sundew (*Drosera*) to prolonged pressure, a singular difference in evident relation to the habits of the two plants. Like the leaves of *Drosera*, however, those of *Dionaea* are completely indifferent to wind and rain. The surface of the blade is very slightly sensitive; it may be roughly handled or scratched without causing movement, but closes when its surface or midrib is deeply pricked or cut. Irritation of the triangular area on each lobe enclosed by the sensitive bristles causes closure. The footstalk is quite insensitive. Inorganic or non-nitrogenous bodies, placed on the leaves without touching the sensitive bristles, do not excite movement, but nitrogenous bodies, if in the least degree damp, cause after several hours the lobes to close slowly. So too the leaf which has closed over a digestible body applies a gradual pressure, which serves to bring the glands on both sides into contact with the body. Thus we see that there are two kinds of movement, adapted for different purposes, one rapid, excited mechanically, the other slow, excited chemically. Leaves made to close over insoluble bodies reopen in less than twenty-four hours, and are ready, even before being fully expanded, to shut again. But if they have closed over nitrogen-yielding bodies, they remain closely shut for many days, and after re-expanding are torpid, and never act again, or only after a considerable time. Even in a state of nature, the most vigorous leaves are very rarely able to digest more than twice, or at most thrice, during their life.

FIG. 3.—A, sensitive bristle and glands of *D. muscipula*, ×50; B, glands, ×300.

VENUS'S LOOKING GLASS, a popular garden name for *Campanula Speculum* (or *Specularia Speculum*), from the old name for the plant, *Speculum Veneris*. It is a common cornfield plant in the south of Europe, and is grown in gardens on account of its brilliant purple flowers.

VERA, AUGUSTO (1813–1885), Italian philosopher, was born at Amelia in the province of Perugia on the 4th of May 1813. He was educated in Rome and Paris, and, after teaching classics for some years in Geneva, held chairs of philosophy in various colleges in France, and subsequently was professor in Strassburg and in Paris. He left Paris after the *coup d'état* of 1851 and spent nine years in England. Attaching himself with enthusiasm to Hegel's system, Vera (who wrote fluently both in French and in English as well as in Italian) became widely influential in spreading a knowledge of the Hegelian doctrine, and became the chief representative of Italian Hegelianism. Without any marked originality, his writings are distinguished by lucidity of exposition and genuine philosophic spirit. In 1860 Vera returned to Italy, where he was made professor of philosophy in the royal academy of Milan. In the following year he was transferred to Naples as professor of philosophy in the university there. His *Prolusioni alla Storia della Filosofia* and *Lezioni sulla Filosofia della Storia* were connected with his professorial work, which was specially devoted to the history of philosophy and the philosophy of history. He held this post till his death, which took place at Naples on the 13th of July 1885.

Among his numerous works may be mentioned *Introduction à la philosophie d'Hégel* (1855; 2nd ed., 1865); *Problème de la certitude* (1845); *Le Hégelianisme et la philosophie* (1861); *Mélanges philosophiques* (1862); *Essais de philosophie Hégélienne* (1864); *Strauss, l'ancienne et la nouvelle foi* (1873), an attack upon Strauss's last "confession," written from the standpoint of an orthodox Hegelian; and a comprehensive work in Italian, *Il Problema dell' Assoluto* (Naples, 1872–82). His English works are an *Inquiry into Speculative and Experimental Science* (London, 1856); *Introduction to Speculative Logic and Philosophy* (St Louis, 1875), and a translation of Bretschneider's *History of Religion and of the Christian Church*. He published also translations into French with commentaries of Hegel's works: *Logique de Hégel* (Paris, 1859; 2nd ed., 1874); *Philosophie de la nature de Hégel* (1863–65); *Philosophie de l'esprit de Hégel* (1867–69); *Philosophie de la religion de Hégel* (1876–78, incomplete).

See R. Mariano, *Augusto Vera* (Naples, 1887) and *Strauss e Vera* (Rome, 1874); Karl Rosenkranz, *Hegel's Naturphilosophie und deren Bearbeitung durch A. Vera* (Berlin, 1868).

VERA CRUZ (officially VERA CRUZ LLAVE), a Gulf Coast state of Mexico, bounded N. by Tamaulipas, W. by San Luis Potosi, Hidalgo, Puebla and Oaxaca, and S.E. by Chiapas and Tabasco. Pop. (1900) 981,030. It is about 50 m. wide, extending along the coast, N.W. to S.E., for a distance of 435 m., with an area of 29,201 sq. m. It was the seat of an ancient Indian civilization antedating the Aztecs and is filled with remarkable and interesting ruins; it is now one of the richest states of the republic. It consists of a low, sandy coastal zone, much broken with tidewater streams and lagoons, behind which the land rises gradually to the base of the sierras and then in rich valleys and wooded slopes to their summits on the eastern margin of the great Mexican plateau, from which rise the majestic summits of Orizaba and Cofre de Perote. The climate is hot, humid and malarial, except on the higher elevations; the rainfall is heavy, and the tropical vegetation is so dense that it is practically impossible to clear it away. At Coatzacoalcos the annual precipitation ranges from 125 to 140 in., but it steadily decreases towards the N. On the higher slopes of the sierras prehistoric terraces are found, evidently constructed to prevent the washing away of the soil by these heavy rains. More than forty rivers cross the state from the sierras to the coast, the following being navigable on their lower courses—Coatzacoalcos, San Juan, Tonto, Papaloapam, Tuxpam and Casones. Several of the lagoons on the coast are also navigable, that of Tamiahua on the northern coast, about 100 m. long, being connected with the port of Tampico by inland channels. There are several ports on the coast—Coatzacoalcos, Alvarado, Vera Cruz, Nautla, Tecolutla and Tuxpam. The products of the state are chiefly agricultural—cotton, sugar, rum, tobacco, coffee, cacao, vanilla, maize, beans and fruit. Cattle-raising is followed in some districts, cattle and hides being among the exports. Among the forest products are rubber, cabinet woods, dye-woods, broom-root, chicle, jalap and orchids. Vera Cruz is one of the largest producers of sugar and rum in Mexico. There are a number of cotton factories (one of the largest in Mexico being at Orizaba), chiefly devoted to the making of coarse cloth for the lower classes. Tobacco factories are also numerous. Other manufactures include paper, chocolate, soap and matches. There are four lines of railway converging at Vera Cruz, two of which cross the state by different routes to converge again at Mexico city. Another, the Tehuantepec National railway, crosses in the south, and is connected with Vera Cruz (city) by the Vera Cruz & Pacific line, which traverses the state in a south-easterly direction. The capital is Jalapa, and its principal towns are Vera Cruz, Orizaba, Cordova and Coatzacoalcos.

VERA CRUZ, a city and seaport of Mexico, in the state of Vera Cruz, on a slight indentation of the coast of the Gulf of Mexico, in 19° 11′ 50″ N., 96° 20′ W., slightly sheltered by some small islands and reefs. Pop. (1900) 29,164. Vera Cruz is the most important port of the republic. It is 263 m. by rail E. of the city of Mexico, with which it is connected by two lines of railway. It is built on a flat, sandy, barren beach, only a few feet above sea-level. The harbour is confined to a comparatively narrow channel inside a line of reefs and small islands, which is exposed to the full force of northern storms. New port works were completed towards the end of the 19th century, which, by means of breakwaters, afford complete protection. In 1905 the four railway companies having terminal stations in Vera Cruz united in the organization of a joint terminal association, with union station, tracks, warehouses, quays, cranes, &c.

Vera Cruz dates from 1520, soon after the first landing there of Cortés. This settlement was called Villa Rica de Vera Cruz, but was soon after moved to the harbour of Bernal, in 1525 to a point now called Old Vera Cruz, and in 1599 to its present site. It was pillaged by privateers in 1653 and 1712, and this led to the erection of the celebrated fort of San Juan de Ulúa, or Ulloa, on one of the reefs in front of the city. In 1838 it was captured by the French, in 1847 (March 29) by an American army under General Winfield Scott, who made Vera Cruz a base for his march upon the city of Mexico, and in 1861 by the French.

VERANDAH, or VERANDA, a roofed gallery or portico attached to the outside of a dwelling-house or other building, usually open at the sides or partially covered by lattice-work or glass or other screens. The roofing is slanting and supported by pillars; a light rail or balustrade often surrounds it. The word in English is comparatively modern, having only been included by Todd in his edition of Johnson's *Dictionary* in 1827. But it was known earlier in India, and the occurrence of the word in modern Hindustani (*varanda*) and Malayan (*baranda*) has led some etymologists to connect the word with the Persian *barāmadan*, to climb. It is, however, certainly of European origin, and was taken to the East by the early Portuguese navigators. It is to be found as early as the end of the 15th century and the beginning of the 16th in Spanish and Portuguese (so Minsheu, "*varanda*, railes to leane the brest on"), and apparently is to be referred to Lat. *vara*, a forked pole or rod.

VERATRUM. The Greek physicians were acquainted with a poisonous herb which they called white hellebore, and which has been supposed to represent the *Veratrum album* of modern botanists. Be this as it may, in modern times the name has been applied to a genus of herbaceous plants belonging to the natural order Liliaceae. *Veratrum* is a tall-growing herb, having a fibrous root-stock, an erect stem, with numerous broad, plicated leaves placed alternately, and terminal, much-branched clusters of greenish or purplish polygamous flowers. Each perfect flower consists of six regular petals, as many stamens, whose anthers open outwardly, and a three-celled superior ovary which ripens into a three-celled, many-seeded capsule. The genus comprises about nine species, natives of the temperate regions of the northern hemisphere, generally growing in pastures or woods. *V. album* and the American species *V. viride* are commonly grown in gardens as ornamental perennials, but their poisonous qualities should be kept in mind, particularly as they bear a considerable resemblance in foliage to the harmless *Gentiana lutea*. Both contain the potent alkaloid veratrine. (See also HELLEBORE.)

VERBENA. The genus *Verbena* (vervain) in botany gives its name to the natural order (Verbenaceae) of which it is a member. The species are herbaceous or somewhat shrubby, erect or procumbent, with opposite or whorled leaves, generally deeply cut. The sessile flowers are aggregated into close spikes. Each flower has a tubular, ribbed calyx, a more or less irregular tubular two-lipped corolla, with four (didynamous) stamens springing from the interior of the corolla-tube. The anthers are two-celled, with or without a gland-like appendage at the apex. The ovary is entire or four-lobed, and always four-celled, with a single ovule in each cell; the style is unequally two-lobed at the apex. The fruit consists of four hard nutlets within the persistent calyx. There are about eighty species known, mostly natives of tropical and subtropical America, a very few species occurring also in the Old World. The vervein, or vervain, *V. officinalis*, native of central and north Asia, Europe and North Africa, and common on dry waste ground in the south of England (rarer in the north), was the object of much superstitious veneration on the part of our pagan ancestors, who attributed marvellous properties to it, provided it were gathered in a particular manner and with much complex ceremonial. The plant is now but lightly esteemed, and its medicinal virtues are wholly discredited. The garden verbenas are derivatives from various South American species, such as *V. teucrioides*, a native of southern Brazil, and *V. chamaedrifolia* from Argentina and southern Brazil. The range of colours extends from pure white to rose-coloured, carmine, violet and purple. Striped forms also are cultivated. The lemon-scented verbena of gardens, so much valued for the fragrance of its leaves, was once referred to this genus under the name *V. triphylla*, subsequently called *Aloysia*, but is now referred to the genus *Lippia* as *L. citriodora*; it differs from *Verbena* in having two, not four, nutlets in the fruit.

The garden verbenas, although somewhat misprized for some years, have once more become popular as bedding plants, and also for pot culture. They are easily raised from seeds sown in heat in February or March, but choice varieties, like Miss Willmott and others, can only be kept true when raised from cuttings. These are best secured from old plants cut down in the autumn and started into growth in gentle heat and moisture the following spring. They root readily in a compost of sandy loam and leaf soil. Besides the garden varieties, *V. venosa*, a Brazilian species with bluish-violet flowers, is a popular plant for massing in beds during the summer months.

VERBÖCZY, ISTVAN [STEPHEN WERBÖCZ] (1465?–1541), Hungarian jurist and statesman, first became known as a scholar and theologian of such eminence that he was appointed to accompany the emperor Charles V. to Worms, to take up the cudgels against Luther. He began his political career as the deputy of the county of Ugocsa to the diet of 1498, where his eloquence and scholarship had a great effect in procuring the extension of the privileges of the gentry and the exclusion of all foreign competitors for the Hungarian throne in future elections. He was the spokesman and leader of the gentry against the magnates and prelates at the diets of 1500, 1501 and 1505. At the last diet he insisted, in his petition to the king, that the law should be binding upon all the gentry alike, and firmly established in the minds of the people the principle of a national monarchy. The most striking proof of his popularity at this time is the fact that the diet voted him two *denarii* per hearth for his services in 1505, a circumstance unexampled in Hungarian history. In 1517 Verböczy was appointed the guardian of the infant Louis II., and was sent on a foreign mission to solicit the aid of Christendom against the Turks. On his return he found the strife of parties fiercer than ever and the whole country in a state of anarchy. At the diet of Hatvan, on the 25th of June 1525, he delivered a reconciliatory oration which so affected the assembly that it elected him palatine. During the brief time he held that high office he unselfishly and courageously endeavoured to serve both king and people by humbling the pride of the magnates who were primarily responsible for the dilapidation of the realm. But he was deposed at the following diet, and retired from public life till the election of János Zapolya, who realized his theory of a national king and from whom he accepted the chancellorship. He now devoted himself entirely to the study of jurisprudence, and the result of his labours was the famous *Opus tripartitum juris consuetudinarii inclyti regni hungariae*, which was the law-book of Hungary till 1848.

See Arpad Karólyi, *Verböczy's Mission to the Diet of Worms* (Hung.; Budapest, 1880); Vilmor Fraknói, *Before and after the Catastrophe of Mohács* (Hung.; Budapest, 1876); ibid., *Stephen Werböczi* (Hung.; Budapest, 1899). (R. N. B.)

VERBOECKHOVEN, EUGÈNE JOSEPH (1799–1881), Belgian painter, was born at Warneton in West Flanders, and received instruction in drawing and modelling from his father, the sculptor Barthélemy Verboeckhoven. Subsequently he settled in Brussels and devoted himself almost exclusively to animal subjects. His paintings of sheep, of horses and of cattle in landscape, somewhat after the manner of Potter, brought him universal fame, and were eagerly sought for by collectors. Precise and careful finish is the chief quality of his art, which is entirely objective and lacking in inspiration. Verboeckhoven visited England in 1826, Germany in 1828, and France and Italy in 1841, and died at Brussels in 1881. He was a member of the academies of Brussels, Ghent, Antwerp, St Petersburg and Amsterdam. Examples of his art are to be found in nearly all the important galleries of Europe and the United States, notably in Brussels, Antwerp, Amsterdam, Hamburg, Berlin, Munich, New York, Boston and Washington. His long life and ceaseless industry account for the enormous number of his pictures in public and private collections and in the art market. In addition to his painted work he executed some fifty etched plates of similar subjects.

VERBRUGGEN, SUSANNA (*c.* 1667–1703), English actress, was the daughter of an actor named Percival, and her first recorded stage appearance was in 1681 in D'Urfey's *Sir Barnaby Whig*. She played at Dorset Garden and the Theatre Royal, and in 1686 married William Mountfort (*q.v.*). By 1690 she was one of the leading actresses in Betterton's company. About a year after Mountfort's death, in 1692, she married John Verbruggen (*fl.* 1688–*c.* 1707), also an actor of considerable ability.

VERCELLI (anc. *Vercellae*), a town and archiepiscopal see of Piedmont, Italy, in the province of Novara, 13 m. S.W. of that town by rail. Pop. (1901) 17,922 (town), 30,470 (commune). It is situated 430 ft. above sea-level on the river Sesia, at its junction with the Canterana. Vercelli is a point at which railways diverge for Novara, Mortara, Casale Monferrato and Santhià (for Turin). The walls by which Vercelli was formerly surrounded have been demolished, and their place is now occupied by boulevards, from which a fine view of the Alps (especially the Monte Rosa group) is obtained. The streets are for the most part tortuous and narrow; there is a large market-place (Piazza Cavour) with a statue of Cavour (1861). The cathedral is a large building dating from the 16th century; its library contains a number of rare ancient MSS., especially the *Codex Vercellensis*, one of the most important MSS. of the old Latin version of the Gospels, written in the 4th or 5th century by Eusebius, bishop of Vercelli. A museum close by contains Roman antiquities. The churches of S. Andrea (a large and fine Romanesque Gothic building dating from 1219–1224, with an interior in the French Gothic style), S. Paolo, S. Caterina and S. Cristoforo possess valuable examples of the work of Gaudenzio Ferrari (1471–1546) and of his follower Lanini. Silk-spinning is important, and Vercelli is one of the principal Italian centres of the exportation of cereals and especially of rice. There are corn and rice mills of large size, while cotton and woollen mills and factories of artificial manure, &c., have attained importance.

Vercellae was originally the chief city of the Libici (a Ligurian tribe) and afterwards became a Roman *municipium* of some importance. It stood at the junction of roads to Eporedia, Novaria and Mediolanum, Laumellum (for Ticinum) and perhaps Hasta. No ancient remains exist above ground, but many inscriptions, tombs and other antiquities have been found. Remains of the theatre and amphitheatre were seen in the 16th century, and remains of ancient streets have more recently been found during drainage operations. There were apparently four principal streets all leading to the centre of the town where the Forum must have been situated. Of the walls, however, nothing is known except from medieval documents (cf. L. Bruzza, *Iscrizioni antiche Vercellesi*, Rome, 1874). In the neighbourhood (near Rotto on the Sesia) are the Raudii Campi where Hannibal won his first victory on Italian soil (218 B.C.), and where in 101 B.C. Marius and Catulus routed the Cimbri. From about 1228 till 1372 Vercelli was the seat of a university. (T. As.)

VERCELLI BOOK (Codex Vercellensis), an Early English MS. containing, besides homilies, a number of poetical and imaginative pieces: *Andreas*, *The Fates of the Apostles*, *Address of the Soul to the Body*, *Falseness of Men*, *Dream of the Rood*, *Elene* and a prose *Life of Guthlac*. It was found in the cathedral library of Vercelli, Piedmont, by a German jurist Friedrich Blume, in 1822, and was first described in his *Iter Italicum* (Berlin and Stettin, 4 vols., 1824–36). An untenable explanation of the presence of the MS. at Vercelli suggested that it had been brought there by Johannes Scotus Erigena. But the handwriting dates from the beginning of the 11th century, long after his death. According to Dr Wülker the MS. probably belonged to the hospice for English pilgrims, founded, together with the monastery of St Andrew, by Cardinal Jacopo Guala-Bicchieri (d. 1227), a native of Vercelli and bishop of the city, in 1219, on his return from England, where he had been papal legate from 1216 to 1218. The cardinal, a man of wide learning, possessed a large library, which he left to the monastery; and the Vercelli codex may well have been included in it.

Its contents were partially printed (by Benjamin Thorpe from Blume's transcript) in Appendix B to C. P. Cooper's *Report of Rymeri Foedera* for 1836; by J. M. Kemble, *The Poetry of the Codex Vercellensis, with an English translation* (Aelfric Soc., 1843–56), and in a better text based directly on the MS. by Wülker in his edition of C. W. M. Grein's *Bibliothek der A.S. Poesie* (Leipzig, 1894), vol. ii. *Codex Vercellensis*, by Dr Richard Wülker (Leipzig, 1894), is a facsimile of the MS.

For the description and history of the MS. see also Wülker's *Grundriss . . . der A.S. Litteratur* (1885), pp. 237–42, and A. Napier in *Zeitschrift für deutsches Altertum* (Berlin, 1889, vol. 21, new series; old series, vol. 33, p. 66), for a collation of Wülker's text with the MS. For the individual poems see also Cynewulf.

VERDEN, a town of Germany, in the Prussian province of Hanover, on the navigable Aller, 3 m. above its confluence with the Weser, 22 m. S.E. of Bremen by the railway to Hanover. Pop. (1900) 9842. The most noticeable edifices are the beautiful Gothic cathedral, the churches of St Andrew and St John, a new Roman Catholic church (1894) and the celebrated cathedral school. Its industries embrace the manufacture of agricultural machinery, cigar-making, brewing and distilling. Verden was the see of a bishopric founded in the first quarter of the 9th century, or earlier, and secularized in 1648. The duchy of Verden was then ceded to Sweden, passed in 1719 to Hanover and in 1810 to the kingdom of Westphalia. It was restored to Hanover in 1814, and was, with Hanover, annexed by Prussia in 1866.

See Ostenberg, *Aus Verden's Vergangenheit* (Stade, 1876).

VERDERER (O. Fr. *verdier*, Med. Lat. *viridarius*), a term used in English forest law for a judicial officer appointed to look after what was known as the "vert" (O. Fr. *verd*, green; Lat. *viridis*), *i.e.* the forest trees and underwood in the royal forests. It was the verderer's duty to keep the assizes and attend to all matters relating to trespasses (see Forest Law).

VERDI, GIUSEPPE FORTUNINO FRANCESCO (1813–1901), Italian composer, was born on the 10th of October 1813 at Le Roncole, a poor village near the city of Busseto. His parents kept a little inn, combined with a kind of village shop. Verdi received some instruction from the village organist, but his musical education really began with his entrance into the house of business of Antonio Barezzi, a merchant of Busseto. Barezzi was a thorough musician, and under his auspices Verdi was speedily introduced to such musical society as Busseto could boast. He studied under Giovanni Provesi, who was *maestro di cappella* of the cathedral and conductor of the municipal orchestra, for which Verdi wrote many marches and other instrumental pieces. These compositions are now the principal treasures of the library of Busseto. Among them is Verdi's first symphony, which was written at the age of fifteen and performed in 1828. In 1832 Verdi went to Milan to complete his studies. He was rejected by the authorities of the Conservatorio, but remained in Milan as a pupil of Vincenzo Lavigna, with whom he worked until the death of Provesi in 1833 recalled him to Busseto. A clerical intrigue prevented him from succeeding his old master as cathedral organist, but he was appointed conductor of the municipal orchestra, and organist of the church of San Bartolomeo. After three years in Busseto, Verdi returned to Milan, where his first opera, *Oberto, Conte di San Bonifacio*, was produced in 1839. His next work, a comic opera, known variously as *Un Giorno di Regno* and *Il Finto Stanislao*, was written in peculiarly distressing circumstances, the composer having had the misfortune to lose his wife and two children in the course of two months. *Un Giorno di Regno* was a complete failure, and Verdi, stung by disappointment, made up his mind to write no more for the stage. He kept his word for a year, but was then persuaded by Merelli, the impresario of La Scala, to look at a libretto by Solera. The poem took his fancy, in a short time the music was written, and in 1842 the production of *Nabucodonosor* placed Verdi in the front rank of living Italian composers. The success of *Nabucodonosor* was surpassed by that of its two successors, *I Lombardi* (1843) and *Ernani* (1844), the latter of which was the first of Verdi's operas to find its way to England. With *Ernani* Verdi became the most popular composer in Europe, and the incessant demands made upon him reacted upon his style. For several years after the production of *Ernani* he wrote nothing which has survived to our time—nothing which deserved to survive. In *Macbeth* (1847) there are passages of some power, and passages too which indicate an approaching transition to a less conventional method of expression. In *Luisa Miller* (1849) also there is a noticeable increase of refinement in style, which contrasts favourably with the melodramatic vulgarity of his earlier manner.

It was unfortunate that *I Masnadieri*, which was written for the English stage and produced under Lumley's management at Her Majesty's Theatre in 1847, should have been one of the worst of the many bad works which Verdi composed at this period of his career. Not the presence of the composer, who travelled to England to conduct the first performance, nor the genius of Jenny Lind, who sang the part of the heroine, could redeem it from failure. In 1851 Verdi won one of the greatest triumphs of his career with *Rigoletto*, a triumph which was fully sustained by the production two years later of *Il Trovatore* and *La Traviata*. In these works Verdi reached the culminating point of what may be called his second manner. His development had been steady though gradual, and it is only necessary to compare the treatment of voice and orchestra in *Rigoletto* with that in *Ernani* to realize how quickly his talent had developed during these seven years. The popularity of *Rigoletto*, *Il Trovatore* and *La Traviata* was enormous, and consolidated Verdi's fame outside the frontiers of Italy. In 1855 he received a commission to write an opera for the Paris Opéra, to be produced during the Universal Exhibition. He wrote *Les Vêpres Siciliennes*, a work which though temporarily successful has not retained its popularity. It contains some fine music, but suffers from the composer's perhaps unconscious attempt to adopt the grandiose manner of French opera. Of the works written during the next ten years only *Un Ballo in Maschera* (1859) has maintained a fitful hold upon public attention. *La Forza del Destino* (1862) and *Don Carlos*, the latter of which was written for the Paris Exhibition of 1867, have the faults incident to works written during a period of transition. At this point in his career Verdi was preparing to emancipate himself from the fetters of conventionality which had hitherto hindered his development. In these two works there are indications of an aspiration towards a freer method of expression, which harmonize ill with the more conventional style of the composer's earlier years. In *Aida*, an opera upon an Egyptian subject, written in response to an invitation from Ismail Pasha, and produced at Cairo in 1871, Verdi entered upon the third period of his career. In this work he broke definitely with the operatic tradition which he had inherited from Donizetti, in favour of a method of utterance, which, though perhaps affected in some degree by the influence of Wagner, still retains the main characteristics of Italian music. In *Aida* the treatment of the orchestra is throughout masterly, and shows a richness of resource which those who knew only Verdi's earlier works scarcely suspected him of possessing; nevertheless, the human voice was still the centre of Verdi's system. Verdi kept thoroughly abreast of modern musical development, but his artistic sense prevented him from falling into the excesses of the German school. In the *Requiem*, which was written in 1874 to commemorate the death of Manzoni, Verdi applied his newly found system to sacred music. His *Requiem* was bitterly assailed by pedants and purists, partly on the ground of its defiance of obsolete rules of musical grammar and partly because of its theatrical treatment of sacred subjects, but by saner and more sympathetic critics, of whom Brahms was not the least enthusiastic, it has been accepted as a work of genius. There are passages in it with which Protestant feeling can scarcely sympathize, but its passionate intensity and dramatic force, and the extraordinary musical beauty with which it abounds, amply atone for what to some may seem errors of taste. In 1881 a revised version of *Simon Boccanegra*, an earlier work which had not been successful, was produced at Milan. The libretto had been in part rewritten by Arrigo Boito, and Verdi wrote a great deal of new music for the revival, which was eminently successful. After this it was generally supposed that Verdi, who had reached an advanced age, had finally relinquished composition, but after a lapse of some years it became known that he was at work upon a new opera, and in 1887 *Otello* was produced at Milan. The libretto, a masterly condensation of Shakespeare's *Othello*, was the work of Boito. *Otello* recalls *Aida* in the general outlines of its structure, but voices and orchestra are treated with greater freedom than in the earlier work, and there is a conspicuous absence of set airs. In so far as regards the essential qualities of the music, *Otello* is an immense advance upon anything Verdi had previously written. It has a dramatic force and a power of characterization for which it would be vain to look in his earlier work, and which are all the more remarkable as appearing for the first time in this high degree of development in a work written in extreme old age. All that has been said of *Otello* may be repeated of *Falstaff*, which was produced in 1893, when the composer was in his eightieth year, with the addition that the later work contains, besides the dramatic power and musical skill of the earlier work, a fund of delicate and fanciful humour which recalls the gayest mood of Mozart. The libretto of *Falstaff*, which is the work of Boito, is an adaptation of *The Merry Wives of Windsor*, with the addition of a few passages from *Henry IV*. After the production of *Falstaff*, Verdi wrote nothing for the stage. In 1898 he produced four sacred pieces, settings of the *Ave Maria, Laudi alla Virgine* (words from Dante's *Paradiso*), the *Stabat Mater* and the *Te Deum*, the first two for voices alone, the last two for voices and orchestra. In these pieces Verdi abandoned to a certain extent the theatrical manner of the *Requiem* for one more restrained and more in keeping with ecclesiastical traditions. In imaginative power and musical beauty these pieces yield to none of Verdi's works. With the exception of these and the *Requiem*, Verdi has written little save for the stage. Among his minor works may be mentioned a string quartet, composed in 1873, a hymn written for the opening of the International Exhibition of 1862, two sets of songs, a *Paternoster* for five-part chorus, and an *Ave Maria* for soprano solo, with string accompaniment. The venerable composer died at Milan on the 27th of January 1901.

The following is a complete list of Verdi's operas, with the dates and places of production: *Oberto* (Milan, 1839); *Un Giorno di Regno* (Milan, 1840); *Nabucodonosor* (Milan, 1842); *I Lombardi* (Milan, 1843); *Ernani* (Venice, 1844); *I Due Foscari* (Rome, 1844); *Giovanna d'Arco* (Milan, 1845); *Alzira* (Naples, 1845); *Attila* (Venice, 1846); *Macbeth* (Florence, 1847); *I Masnadieri* (London, 1847); *Il Corsaro* (Trieste, 1848); *La Battaglia di Legnano* (Rome, 1849); *Luisa Miller* (Naples, 1849); *Stiffelio* (Trieste, 1850); *Rigoletto* (Venice, 1851); *Il Trovatore* (Rome, 1853); *La Traviata* (Venice, 1853); *Les Vêpres Siciliennes* (Paris, 1855); *Simon Boccanegra* (Venice, 1857; revised version, Milan, 1881); *Aroldo* [a revised version of *Stiffelio*] (Rimini, 1857); *Un Ballo in Maschera* (Rome, 1859); *La Forza del Destino* (St Petersburg, 1862); *Don Carlos* (Paris, 1867); *Aida* (Cairo, 1871); *Otello* (Milan, 1887); *Falstaff* (Milan, 1893). (R. A. S.)

VERDICT (O. Fr. *verdit*, Lat. *vere dictum*, truly said, used in Late Latin in one word with its present significance), the decision of a jury in a criminal or civil cause, given to the court through the foreman of the jury and recorded. In English law verdicts may be "general," *i.e.* in criminal cases "guilty" or "not guilty," or "special," when there is some question of law which the jury wish to leave to the consideration of the court; in this case the verdict is given in the form of a statement of facts as found by the jury, and the issue is left to be found by the court in accordance with the law upon such facts as found (see JURY).

VERDIGRIS, a pigment, consisting of basic copper carbonates, made by acting upon copper plates with pyroligneous acid soaked up in cloths, exposing the plates to air, then dipping in water, and finally scraping off the greenish crust; the plate is re-exposed and the operation repeated till it is used up. Another method consists in exposing thin copper sheets to the acid vapours rising from the residues or "marcs" of wine factories, the product being scraped off, and the plate re-exposed. Both processes require several weeks. The pigment appears with several shades of blue and green; blue verdigris is chiefly $CuO \cdot Cu(C_2H_3O_2)_2 \cdot 6H_2O$, while light blue and green verdigris contain $2CuO \cdot Cu(C_2H_3O_2)_2 \cdot 2H_2O$. Besides being used as a paint it is employed in dyeing and calico-printing, and also in the manufacture of other paints, *e.g.* Schweinfurt green, which is a double salt of the acetate and arsenite. A liniment or ointment is also used in medicine as a cure for warts. It is an irritant poison (hence the need that acid substances should never be cooked in copper utensils); the best antidote is white of egg and milk.

VERDUN, a garrison town of north-eastern France, capital of an arrondissement in the department of Meuse, on the main line of the Eastern railway between Paris and Metz, 42 m. N.N.E. of Bar-le-Duc. Pop. (1906) 12,837. In addition the population *comptée à part* (soldiers, &c.) numbers 8198. Verdun is situated in a basin surrounded by vine-clad hills on the Meuse, which here forms the Eastern Canal.

Verdun as a fortress is of first-rate importance. It lies directly opposite the frontier of German Lorraine and the great entrenched camp of Metz. At the time of the war of 1870 (when it was defended for long without hope of success by General Guérin de Waldersbach) it was still a small antiquated fortress of the Vauban epoch, but in the long line of fortifications on the Meuse created by Serré de Rivière in 1875 Verdun, forming the left of the "Meuse Line" barrier, was made the centre of an entrenched camp. The first lesson of 1870 being taken to heart, forts were placed (Belrupt S.E., St Michel N.E., Belleville N. and La Chaume and Regret W.) on all the surrounding heights that the besiegers had used for their batteries, but the designers soon extended the line of the eastern defences as far out as the sharply defined cliffs that, rising gently for some miles from the Meuse, come to an abrupt edge and overlook the plain of Woëvre. On this front, which is about $5\frac{1}{2}$ m.

long, the most important works are (from right to left) Châtillon, Manezel, Moulainville, Eix, Mardi Gras, Lanfée, Vaux and Hardimont. At right angles to this line, the south front, the works of which are placed along one of the long western spurs of the line of heights, are forts Rozellier, St Symphorien and Haudainville, the last overlooking the Meuse. The north front, also on a spur of the ridge, is thickly studded with forts, these in some cases being but 200 yds. apart and the left fort overlooking the Meuse. Behind the east front, chiefly designed to close the valley by which the Metz-Verdun railway penetrates the line of heights, are Fort Tavannes with its outworks and a series of batteries on the adjacent spurs. On the left bank of the Meuse there is a complete semicircle of forts. At the northern end of this semicircle (besides some works in the valley itself), and crossing its fire with the left of the north front, is Fort Belle-Épine, then comes Marre, Bourrus and Bruyères, all four being on a single ridge facing N.W. The west front is composed of Fort Germonville, Fort Bois de Sartelles, Fort Bois du Chapitre, Fort Landrecourt and Fort Dugny, which last is within sight of Fort Haudainville over the Meuse. In second line behind these works are Fort Choisel, Chana redoubt and Fort Sartelles. In all there are 16 large forts and about 20 smaller works, the perimeter of the whole being about 30 m. and the greatest diameter of the fort-ring 9.

The chief quarter of the town lies on the slope of the left bank of the river and is dominated by the citadel which occupies the site of the old abbey of St Vanne founded in the 10th century. Several arms of the river intersect the quarter on the right bank. The whole town is surrounded by a bastioned enceinte, pierced by four gates; that to the N.E., the Porte Chaussee, flanked by two crenelated towers, is an interesting specimen of the military architecture of the 15th century. The cathedral of Notre-Dame stands on the site of two previous churches of the Romanesque period, the first of which was burnt down in 1047; a crypt and other remains of the second building consecrated in 1147 are still to be seen, but the greater part of the present church dated from subsequent periods. Built under the influence of Rhenish architecture, Notre-Dame has double transepts and, till the 18th century when the western apse was replaced by a façade, had an apse at each extremity. A fine cloister to the S.W. of the cathedral dates from the 15th century. The hôtel-de-ville (17th century) contains the museum.

Verdun is the seat of a bishop and a sub-prefect and has tribunals of first instance and of commerce, a communal college, ecclesiastical seminaries and a branch of the Bank of France. The industries include metal founding, the manufacture of sweetmeats (*dragées de Verdun*), machinery, nails, files, embroidery, linen, chairs and rope and the distillation of liqueurs. The canal port has trade in timber, agricultural produce, stone and building materials and coal.

Verdun (*Verodunum*), an important town at the time of the Roman conquest, was made a part of Belgica Prima. The bishopric, of which the most celebrated holder was St Vanne (498–525), dates from the 3rd century. Verdun was destroyed during the period of the barbarian invasions, and did not recover till towards the end of the 5th century. Clovis seized the town in 502, and it afterwards belonged to the kingdom of Austrasia. In 843 the famous treaty was signed here by the sons of Louis the Pious (see GERMANY, *History*). In the 10th century Verdun was definitively conquered by Germany and put under the temporal authority of its bishops. Together with Toul and Metz, the town and its domain formed the territory of the Trois-Évêchés. In the 11th century the burghers of the now free and imperial town began a struggle with their bishops, which ended in their obtaining certain rights in the 12th century. In 1552 Henry II. of France took possession of the Trois-Évêchés, which finally became French by the treaty of Westphalia. In 1792, after some hours of bombardment, the citizens opened their gates to the Prussians—a weakness which the Revolutionary Government punished by the execution of several of the inhabitants. In 1870 the Prussians, unable to seize the town by a *coup de main*, invested and bombarded it three different times, till it capitulated in the beginning of November.

VERDY DU VERNOIS, JULIUS VON (1832–), German general and military writer, was born in 1832 and entered the Prussian infantry in 1850. After some years of regimental service he came under the notice of Moltke, the newly appointed chief of the general staff, as an exceptionally gifted soldier, and at the outbreak of the war against Austria in 1866 he was appointed major on the staff of the II. Army (crown prince of Prussia). In this capacity he took part in the campaign on the upper Elbe and in the battle of Königgrätz. Promoted shortly after this to the rank of lieutenant-colonel, he was in 1867 placed at the head of a section of the general staff, becoming thereby one of Moltke's principal confidential assistants. In this capacity he served at the headquarters of the German army throughout the war of 1870–71, and he was frequently employed in the most important missions, as for instance on the 2nd of August, when he was sent to impress upon the III. Army headquarters the necessity of a prompt advancing into Alsace, and on the 26th of the same month, when he was sent to advise the crown prince of Saxony as to the strategical intentions of the supreme command at the crisis of the Sedan campaign. At the close of the war he continued to serve in the office of the general staff, and also lectured at the War Academy. It was in the latter position that he developed the system of thorough tactical education which is the abiding result of his work. His method may be studied in English translations of his *Studies in Troop-leading*, and may be summarized as the assumption of an actual military situation on the actual ground, followed by critical discussion of the successive measures that a commander, whether of a brigade, division or larger force, should take in the sequel, given his orders and his knowledge of the general situation. Moltke's own series of tactical problems, extending from 1859 to 1889, contributed very powerfully, of course, to the education of the selected young officers who passed through Verdy's hands, but Moltke dealt rather with a great number of separate problems, while Verdy developed in detail the successive events and ruling ideas of a whole day's or week's work in the same units. Moltke therefore may be said to have developed the art of forming correct ideas and plans, Verdy that of applying them, but these are after all merely tendencies, not sharply divided schemes, in the teaching of Prussian staff officers during the years of intellectual development between 1870 and 1888. In all this Moltke, Verdy and Bronsart von Schellendorf worked in close co-operation. In 1876 Verdy became a major-general, from 1879–1883 he held an important position in the ministry of war, and in 1881 he was promoted lieutenant-general. In 1887 he became governor of Strassburg, in 1888 general of infantry and in 1889 minister of war. He retired from the active list in 1890. In 1894 the university of Königsberg made him a Dr. Phil. *honoris causa*.

General von Verdy du Vernois's principal writings are: *Theilnahme der II. Armee am Feldzuge 1866* (Berlin, 1866); *Im Hauptquartier der II. Armee 1866* (Berlin, 1900); *Studien über den Krieg auf Grundlage . . . 1870/1* (Berlin, 1892–96); *Im grossen Hauptquartier 1870/1* (Berlin, 1895; English translation); *Studien über Truppenführung* (Berlin, 1870; new edition, 1892, English translation) and *Studien über den Krieg* (Berlin, 1901–1906).

VERE, the family of which is extolled by Macaulay as "the longest and most illustrious line of nobles that England has seen," appears to have derived the surname which the verse of Tennyson has made synonymous with ancient blood, from the little village of Ver near Bayeux. Its founder, Aubrey (Albericus) de Vere, appears in Domesday Book (1086) as the holder of a great fief in Essex, Cambridgeshire and Suffolk. His son (or grandson) and namesake was a trusted officer of Henry I., from whom he received the hereditary office of great chamberlain in 1133. It was probably he who erected the noble tower which gave name to Castle Hedingham, Essex, the head of his fief, and which stands as the finest example of a private Norman keep. Slain in 1141, he was succeeded by his son Aubrey, who had already become count of Guînes, in right of his wife, on her grandfather's death. Through the powerful influence of his sister's husband, Geoffrey, earl of Essex, he obtained from the empress Matilda, in 1142, the earldom of Oxford, which was afterwards confirmed to his house by Henry II. His younger son, Robert (*c.* 1170–1221), became 3rd earl in 1214, and, siding with the barons, became one of the twenty-five executors of Magna Carta. His marriage with a Bolebec heiress brought in what was afterwards claimed as a barony, and led to the style of Viscount Bolebec (or Bulbeck) for the earl's heirs.

Robert, the 5th earl (1240–1296), who brought into his family the chamberlainship to the queen by his marriage with the Sandford heiress, sided with Simon de Montfort, and lost for a time his earldom and offices. John, the 7th earl (1313–1360), was a distinguished soldier, fighting at Creçy and Poitiers and in all Edward III.'s wars in his time; and his marriage with a Badlesmere heiress added to the lands and titles of his house. His son, Thomas (1337–1371), also a soldier, was father of Robert, 9th earl, the famous favourite of Richard II. In spite of his attainder (1388), his uncle Aubrey (*c.* 1340–1400), a follower of the Black Prince, was restored to the earldom, by consent of parliament in 1393, but not to the great chamberlainship. As the earldom (which had been held in fee) was granted to him in tail male, this is looked on by some as a new creation. His elder son, Richard (d. 1417), the next earl, held a command at Agincourt, and was father of Earl John, who was beheaded as a Lancastrian, with his eldest son, in 1462. Their death was avenged by his younger son John, the 13th earl (1443–1513), who shared to the full in the triumph of the Red Rose. On the death of his nephew John, the next earl (d. 1526), the baronies (it was afterwards held) passed away to his sisters, but the earldom descended to his cousin John (d. 1540), though the crown resumed the great chamberlainship. This John, who was in favour with Henry VIII., was grandfather, through his younger son Geoffrey, of the celebrated "fighting Veres," Sir Francis and his brother Sir Horace. His eldest son John, 16th earl (*c.* 1512–1562), was in favour with Edward VI., Mary and Elizabeth, and contrived to recover for his family the office of great chamberlain.

Hitherto the earls, in spite of their vicissitudes, had retained possession of their ancient seat and great estates; but Edward, the son of Earl John, was a spendthrift. A brilliant, gifted courtier, in whom Elizabeth delighted, he quarrelled with his father-in-law, Burghley, "sent his patrimony flying," patronized players, poets and musicians, and wrote excellent verse himself. His son Henry, the 18th earl (1593–1625), was twice imprisoned in the Tower as an opponent of Buckingham's policy, fought in the Palatinate and the Low Countries and died on campaign at the Hague in 1625. Then ensued the great dispute for the inheritance of his title and office (Hedingham Castle having passed away) between Robert Vere, his second cousin and heir-male, and Robert, Lord Willoughby d'Eresby, son of his aunt, Lady Mary Vere. The earldom was secured by the former, a poor officer in Holland, but the office was adjudged to Lord Willoughby, in whose descendants it is now vested. Earl Robert was slain before Maestricht in 1632, leaving an only son, Aubrey (1626–1703), 20th and last earl. His marriage with a Bayning heiress restored the fortunes of his house, and his Royalist intrigues under the Commonwealth were rewarded at the Restoration by sundry favours, among them the command of a regiment of horse, known from him as "the Oxford Blues" and still familiar as "the Blues" (Royal Horse Guards). James II. deprived him of his regiment and his lieutenancy of Essex for opposing his policy, but the prince of Orange, whom he joined, restored them. His long tenure of the ancient earldom ended in 1703, when he died, the last known male descendant of the house of Vere. His daughter Diana having married the 1st duke of St Albans, their descendants are named De Vere Beauclerk, and received the barony of Vere (1705).

The halo surrounding the name of Vere is seen as early as 1626 in the stately panegyric of Chief Justice Crewe. "I suppose there is no man that hath any apprehension of gentry, or nobleness, but his affection stands to the continuance of so noble a name and house." In the great days of the house, Earl John, says Stowe, rode into London city "with eighty gentlemen in a livery of Reading tawney, and chains of gold about their necks, before him, and one hundred tall yeomen in the like livery to follow him," wearing the famous badge of the blue boar (*verres*), which is still to be seen in Essex churches and forming the sign of Essex inns. Another badge of the Veres was the mullet in the first quarter of their shield, which, at Barnet Field, by a fatal error, was taken for the sun of York. Among the offices they held were the forestership of Essex and the keepership of Colchester Castle, and they founded the Essex religious houses of Hatfield Broadoak, Hedingham and Earls Colne.

Authorities.—Domesday Book; Abingdon Chron. and Red Book of the Exchequer (Rolls Series); Pipe Roll of 1130 (Record Commission); Dugdale's *Baronage*; G. E. C(okayne)'s *Complete Peerage*; Doyle's *Official Baronage*; Collins's *Historical Precedents*; Morant's *History of Essex*; Round's *Geoffrey de Mandeville and Feudal England*; Nichols's "Descent of the Earldom of Oxford" (*Arch. Journ.* vol. ix.); Vere papers among the Round MSS. in App. ix. to *14th Report on Historical MSS.*; *Lords' Reports on the Dignity of a Peer*; Palmer's *Peerage Law in England*. The claimants' cases and the appendices of documents in the contest for the great chamberlainship (1902) are valuable for the history of the Veres. (J. H. R.)

VERE, SIR FRANCIS (1560–1609), English soldier, was the son of Geoffrey Vere of Crepping Hall, Essex, and nephew of the 16th earl of Oxford. He first went on active service under Leicester in 1585, and was soon in the thick of the war raging in the Low Countries. At the siege of Sluys young Vere greatly distinguished himself under Sir Roger Williams and Sir Thomas Baskerville. In 1588 he was in the garrison of Bergen-op-Zoom, which delivered itself from the besiegers by its own good fighting, and was knighted by Willoughby on the field of battle. In the next year Sir Francis became sergeant-major-general of the English troops in the Low Countries, and soon afterwards the chief command devolved upon him. This position he retained during fifteen campaigns, with almost unbroken success. Working in close co-operation with the Dutch forces under Maurice, he step by step secured the country for the cause of independence. Vere won the reputation of being the first soldier of the day, his English troops acquired a cohesion and training fitting them to face the best Spanish troops, and his camp became the fashionable training-ground of all aspiring soldiers, amongst others not only his brother Horace, but men of such note as Ferdinando (Lord) Fairfax, Gervase Markham and Miles Standish. Sir Francis served in the Cadiz expedition of 1596, and in 1598 was entrusted with the negotiation of the treaty whereby the Dutch agreed to take a greater share of the burden of the war than they had hitherto done. His success in this task obtained him the governorship of Brill and the rank of general. The culminating point of his career came when, in 1600, on the advice of Barneveld, the states general decided to carry the war into the enemy's country. In the battle of Nieuwport (2nd July 1600), one of the most desperately contested battles of the age, Vere and Maurice completely defeated the veteran Spanish troops of the archduke Albert. This was followed by the celebrated defence of Ostend from July 1601 to March 1602. When James I. made peace with Spain, Vere retired from active service and spent the remainder of his days in country life in England, occupying himself with the compilation of his *Commentaries of the Divers Pieces of Service wherein he had Command* (1657; reprinted in Arber's *English Garner*, 1883). He died in 1609, soon after the truce recognized the independence of the United Provinces, and was buried in Westminster Abbey.

His younger brother Sir Horace Vere, Baron Vere of Tilbury (1565–1635), began his military career as the lieutenant of Sir Francis's Company in 1590. Thenceforward he was continually on active service in the Low Countries, and, like his brother, took part in the Cadiz expedition of 1596; at Nieuwport and Ostend Sir Horace (who had been knighted at Cadiz) held command of some importance. On his brother's retirement Sir Horace, as senior colonel, assumed command of the whole English force, which he held until 1607, being opposed to Ambrosio Spinola, the most famous of the continental generals of the time, against whom he manœuvred and fought in a manner equal to the best of his brother's, or even of Parma's, work. From 1607 to 1620 he saw but little active service except the siege of Jülich (1610). In 1620 he accepted the command of the volunteers who were going to the assistance of the Elector Palatine. This famous expedition to the Rhine and the Main was from the first a forlorn hope. Opposed by his old adversary Spinola, Vere manœuvred with success for two campaigns, but he was helpless against the armies of Tilly and Cordova, and in the end he could only furnish scanty garrisons for Frankenthal, Heidelberg and Mannheim. Each of these places fell after a desperate resistance, and their garrisons returned to England. In 1624 Vere was once more on service in the United Provinces. The attempted relief of Breda in the following year was considered one of the most brilliant feats of the time, and the general was made Baron Vere of Tilbury. In 1629 the sieges of Bois-le-duc (s'Hertogenbosch) and of Maestricht closed his military career. Lord Vere died suddenly in 1635 and was buried by the side of his brother in Westminster Abbey.

See Clements C. Markham, *The Fighting Veres* (London, 1888).

VERESHCHAGIN, VASSILI VASSILIEVICH (1842–1904), Russian artist and traveller, was born at Tcherepovets, in the government of Novgorod, on the 26th of October 1842. His father was a Russian landowner of noble birth, and from his mother he inherited Tatar blood. When he was eight years old he was sent to Tsarskoe Selo to enter the Alexander cadet corps, and three years later he entered the naval school at St Petersburg, making his first voyage in 1858. He graduated first in the list from the naval school, but left the service immediately to begin the study of drawing in earnest. He won a medal two years later, in 1863, from the St Petersburg Academy for his ".Ulysses slaying the Suitors." In 1864 he proceeded to Paris, where he studied under Gérôme, though he dissented widely from his master's methods. In the Salon of 1866 he exhibited a drawing of "Doukhobors chanting their Psalms," and in the next year he accompanied General Kauffmann's expedition to Turkestan, his military service at the siege of Samarkand procuring for him the cross of St George. He was an indefatigable traveller—in Turkestan in 1869, the Himalayas, India and Tibet in 1873, and again in India in 1884. After a period of hard work in Paris and Munich he exhibited some of his Turkestan pictures in St Petersburg in 1874, among them two which were afterwards suppressed on the representations of Russian soldiers— "The Apotheosis of War," a pyramid of skulls dedicated "to all conquerors, past, present and to come," and "Left Behind," the picture of a dying soldier deserted by his fellows. Vereshchagin was with the Russian army during the Turkish campaign of 1877; he was present at the crossing of the Shipka Pass and at the siege of Plevna, where his brother was killed; and he was dangerously wounded during the preparations for the crossing of the Danube near Rustchuk. At the conclusion of the war he acted as secretary to General Skobelev at San Stefano. After the war he settled at Munich, where he produced his war pictures so rapidly that he was freely accused of employing assistants. The sensational subjects of his pictures, and their didactic aim —the promotion of peace by a representation of the horrors of war—attracted a large section of the public not usually interested in art to the series of exhibitions of his pictures in Paris in 1881 and subsequently in London, Berlin, Dresden, Vienna and other cities. He aroused much controversy by his series of three pictures of a Roman execution (the Crucifixion), of sepoys blown from the guns in India, and of the execution of Nihilists in St Petersburg. A journey in Syria and Palestine in 1884 furnished him with an equally discussed set of subjects from the New Testament. The "1812" series on Napoleon's Russian campaign, on which he also wrcte a book, seem to have been inspired by Tolstoi's *War and Peace*, and were painted in 1893 at Moscow, where the artist eventually settled. Vereshchagin was in the Far East during the Chino-Japanese War, with the American troops in the Philippines, and with the Russian troops in Manchuria. He perished in the sinking of the Russian flagship, "Petropavlovsk," on the 13th of April 1904. His last work, a picture of a council of war presided over by Admiral Makaroff, was recovered almost uninjured.

See E. Zabel, "Wereschtschagin" (1900), in Knackfuss's *Künstlermonographien* (Bielefeld and Leipzig). The finest collection of his pictures is in the Tretiakov gallery in Moscow.

VERGA, GIOVANNI (1840–), Italian novelist, was born at Catania, Sicily. In 1865 he published *Storia di una peccatrice* and *I Carbonari della montagna*, but his literary reputation was established by his *Eva* and *Storia di una capinera* (1869). Other novels followed, the best of which are *Malavoglia* (1881) and *Maestro Don Gesualdo* (1889). His finest work, however, is seen in his short stories and sketches of Sicilian peasantry, *Medda* (1874) and *Vita dei campi* (1880); and his *Cavalleria Rusticana* acquired new popularity from its dramatization and from Mascagni's opera on this subject. Verga and Fogazzaro between them may be said to have faithfully chronicled the inner and popular life of southern and northern Italy.

VERGE (Lat. *virga*, a rod), originally a staff denoting authority, whence (from the ceremony in swearing fealty to a lord) the sense of a measurement, and so boundary or border, of land, or generally a margin of space. In architecture, a verge is the edge of the tiling projecting over the gable of a roof; that on the horizontal portion being called "eaves." The term "verge board," generally now known as barge board, is the name given to the board under the verge of gables, sometimes moulded, and often very richly carved, perforated and cusped, and frequently having pendants and sometimes finials at the apex.

VERGENNES, CHARLES GRAVIER, Comte de (1717–1787), French statesman, was born at Dijon on the 20th of December 1717. He was introduced to the profession of diplomacy by his uncle, M. de Chavigny, under whom he saw his first service at Lisbon. His successful conduct of French interests at the court of Trier in 1750 and the following years led to his being sent to Constantinople in 1755 at first as minister plenipotentiary, then as ambassador. In 1768 he was recalled, ostensibly because of a mésalliance with Mme Testa, widow of a Pera surgeon, but really because Choiseul thought him not zealous enough in provoking a quarrel between Russia and Turkey. After Choiseul's death he was sent to Stockholm with instructions to help the aristocratic party of the "Hats" with advice and money. The revolution by which Gustavus III. (August 19, 1772) secured for himself the reality instead of the shadow of power was a great diplomatic triumph for France. With the accession of Louis XVI. Vergennes became foreign minister. His general policy was one of friendly relations with Austria, combined with the limitation of Joseph II.'s ambitious designs; the protection of Turkey; and opposition at all points to England. His hatred of England and his desire to avenge the disasters of the Seven Years' War led to his support of the American States in the War of Independence, a step of which the moral and financial results had not a little to do with the Revolution of 1789. Vergennes sought by a series of negotiations to secure the armed neutrality of the Northern Powers eventually carried out by Catherine II.; he ceded to the demands of Beaumarchais that France should secretly provide the Americans with arms and volunteers. In 1777 he informed the American commissioners that France acknowledged the Republic and was willing to form an offensive and defensive alliance with the new state. In domestic affairs Vergennes belonged to the old school. He intrigued against Necker, whom he regarded as a dangerous innovator, a republican, a foreigner and a Protestant. In 1781 he became chief of the council of finance, and in 1783 he supported the nomination of Calonne as controller general. Vergennes died on the 13th of February 1787, before the meeting of the Assembly of Notables which he is said to have suggested to Louis XVI.

See P. Fauchelle, *La Diplomatie française et la Ligue des neutres de 1780* (1776–83) (Paris, 1893); John Jay, *The Peace Negotiations of 1782–83 as illustrated by the Confidential Papers of Shelburne and Vergennes* (New York, 1888); L. Bonneville de Marsangy, *Le Chevalier de Vergennes, son ambassade à Constantinople* (Paris, 1894), and *Le Chevalier de Vergennes, son ambassade en Suède* (Paris, 1898).

VERGER (M.E. *vergere*; O. Fr. *vergier*; Med. Lat. *virgarius*, one who bears a rod or staff, an apparitor; Lat. *virga*, rod), one who carries a "verge" or staff of office. The principal use of the term is ecclesiastical, and refers to the person who carries a staff as a symbol of office before a bishop or other church dignitary when taking part in a service, especially one held in a cathedral. The word has thus come to mean in general usage an official caretaker of any place of worship whose duty it is to show the building to those who wish to view it, and to find seats for the congregation at a service.

VERGNIAUD, PIERRE VICTURNIEN (1753–1793), French orator and revolutionist, was born on the 31st of May 1753 at Limoges. He was the son of a merchant of that town who lost the greater part of his means by speculation. The boy was early sent to the college of the Jesuits at Limoges, and soon achieved distinction. Turgot was then intendant of Limousin. In his presence young Vergniaud on one occasion recited some verses of his own composition. Turgot was struck with the talent they displayed, and by virtue of his patronage Vergniaud, having gone to Paris, was admitted to the college of Plessis. It is impossible to read the speeches of Vergniaud without being convinced of the solidity of his education, and in particular of the wide range of his knowledge of the classics, and of his acquaintance—familiar and sympathetic—with ancient philosophy and history.

Duputy, president of the parlement of Bordeaux, with whom Vergniaud became acquainted, conceived the greatest admiration and affection for him and appointed him his secretary. Vergniaud was thereafter called to the bar (1782). The influence of Duputy gained for him the beginnings of a practice; but Vergniaud, though capable of extraordinary efforts, too often relapsed into reverie, and was indisposed for study and sustained exertion, even in a cause which he approved. This weakness appears equally in his political and in his professional life: he would refuse practice if his purse were moderately well filled; he would sit for weeks in the Assembly in listlessness and silence, while the policy he had shaped was being gradually undermined, and then rise, brilliant as ever, but too late to avert the calamities which he foresaw. In 1789 Vergniaud was elected a member of the general council of the department of the Gironde. Being deeply stirred by the best ideas of the Revolutionary epoch, he found a more congenial sphere for the display of his great powers in his new position. About this period he was charged with the defence of a member of the national guard of Brives, which was accused of provoking disorders in the department of La Corrèze. Abandoning all reserve, Vergniaud delivered one of the great orations of his life, depicting the misfortunes of the peasantry in language of such combined dignity, pathos and power that his fame as an orator spread far and wide.

Vergniaud was chosen a representative of the Gironde to the National Legislative Assembly in August 1791, and he forthwith proceeded to Paris. The Legislative Assembly met on the 1st of October. For a time, according to his habit, he refrained from speaking; but on the 25th of October he ascended the tribune, and he had not spoken long before the whole Assembly felt that a new power had arisen which might control even the destinies of France. This judgment was re-echoed outside, and he was almost immediately elected president of the Assembly for the usual brief term. Between the outbreak of the Revolution and his election to the Legislative Assembly the political views of Vergniaud had undergone a decided change. At first he had lauded a constitutional monarchy; but the flight of Louis XVI. filled him with distrust of the sovereign, and his views in favour of a republic were rapidly developed. The sentiments and passions which his eloquence aroused were, however, watchfully utilized by a more extreme party. It happened thus even with his first Assembly speech, on the *émigrés*. His proposal was mainly that a treble annual contribution should be levied on their property; but the Assembly confiscated their goods and decreed their deaths. One great blot on his reputation is that step by step he was led on to palliate violence and crime, to the excesses of which his eyes were only opened by the massacres of September, and which ultimately overwhelmed the party of Girondists which he led. The disgrace to his name is indelible that on the 19th of March 1792, when the perpetrators of the massacre of Avignon had been introduced to the Assembly by Collot d'Herbois, Vergniaud spoke indulgently of their crimes and lent the authority of his voice to their amnesty. In language sometimes turgid, but nearly always of pure and powerful eloquence, he worked at the theme of the *émigrés*, as it developed into that of the counter-revolution; and in his occasional appearances in the tribune, as well as in the project of an address to the French people which he presented to the Assembly on the 27th of December 1791, he shook the heart of France, and, especially by his call to arms on the 18th of January, shaped the policy which culminated in the declaration of war against the king of Bohemia and Hungary on the 20th of April. This policy in foreign affairs, which he pursued through the winter and spring of 1791–92, he combined with another—that of fanning the suspicions of the people against the monarchy, which he identified with the counter-revolution, and of forcing on a change of ministry. On the 10th of March Vergniaud delivered a powerful oration in which he denounced the intrigues of the court and uttered his famous apostrophe to the Tuileries: "In ancient times fear and terror have often issued from that famous palace; let them re-enter it to-day in the name of the law!" The speech overthrew De Lessart, whose accusation was decreed; and Roland, the nominee of the Girondists, entered the ministry. By the month of June the opposition of Vergniaud (whose voice still commanded the country) to the king rose to fever heat. On the 29th of May Vergniaud went so far as to support the disbanding of the king's guard. But he appears to have been unaware of the extent of the feelings of animosity which he had done much to arouse in the people, probably because he was wholly unconnected with the practices of the party of the Mountain as the instigators of actual violence. This party used Vergniaud, whose lofty and serene ideas they applauded and travestied in action. Then came the riot of the 20th of June and the invasion of the Tuileries. He rushed among the crowd, but was powerless to quell the tumult. Continuing for yet a little longer his course of feverous, almost frenzied, opposition to the throne, on the 3rd of July he electrified France by his bold denunciation of the king, not only as a hypocrite and a despot, but as a base traitor to the constitution. His speeches breathe the very spirit of the storm, and they were perhaps the greatest single factor in the development of the events of the time. On the 10th of August the Tuileries was stormed, and the royal family took refuge in the Assembly. Vergniaud presided. To the request of the king for protection he replied in dignified and respectful language. An extraordinary commission was appointed: Vergniaud wrote and read its recommendations that a National Convention be formed, the king be provisionally suspended from office, a governor appointed for his son, and the royal family be consigned to the Luxembourg. Hardly had the great orator attained the object of his aim—the overthrow of Louis as a sovereign—when he became conscious of the forces by which he was surrounded. He denounced the massacres of September—their inception, their horror and the future to which they pointed—in language so vivid and powerful that it raised for a time the spirits of the Girondists, while on the other hand it aroused the fatal opposition of the Parisian leaders.

The questions whether Louis XVI. was to be judged, and if so by whom, were the subject of protracted debate in the Convention. They were of absorbing interest to Paris, to France and to Europe; and upon them the Girondist leader at last, on the 31st of December 1792, broke silence, delivering one of his greatest orations, probably one of the greatest combinations of sound reasoning, sagacity and eloquence which has ever been displayed in the annals of French politics. He pronounced in favour of an appeal to the people. He pictured the consequences of that temper of vengeance which animated the Parisian mob and was fatally controlling the policy of the Convention, and the prostration which would ensue to France after even a successful struggle with a European coalition, which would spring up after the murder of the king. The great effort failed; and four days afterwards something happened which still further endangered Vergniaud and his whole party. This was the discovery of a note signed by him along with Gaudet and Gensonné and presented to the king two or three weeks before the 10th of August. It contained nothing but sound and patriotic suggestions, but it was greedily seized upon by the enemies of the Gironde as evidence of treason. On the 16th of January 1793 the vote began to be taken in the Convention upon the punishment of the king. Vergniaud voted early, and voted for death. The action of the great Girondist was and will always remain inscrutable, but it was followed by a similar verdict from nearly the whole party which he led. On the 17th Vergniaud presided at the Convention, and it fell to him, labouring under the most painful excitement, to announce the fatal result of the voting. Then for many weeks he sank, exhausted, into silence.

When the institution of a revolutionary tribunal was proposed, Vergniaud vehemently opposed the project, denouncing the tribunal as a more awful inquisition than that of Venice, and avowing that his party would all die rather than consent to it. Their death by stratagem had already been planned, and on the 10th of March they had to go into hiding. On the 13th Vergniaud boldly exposed the conspiracy in the Convention. The antagonism caused by such an attitude had reached a significant point when on the 10th of April Robespierre himself laid his accusation before the Convention. He fastened especially upon Vergniaud's letter to the king and his support of the appeal to the people as a proof that he was a moderate in its then despised sense. Vergniaud made a brilliant extemporaneous reply, and the attack for the moment failed. But now, night after night, Vergniaud and his colleagues found themselves obliged to change their abode, to avoid assassination, a price being even put upon their heads. Still with unfaltering courage they continued their resistance to the dominant faction, till on the 2nd of June 1793 things came to a head. The Convention was surrounded with an armed mob, who clamoured for the "twenty-two." In the midst of this it was forced to continue its deliberations. The decree of accusation was voted, and the Girondists were proscribed.

Vergniaud was offered a safe retreat. He accepted it only for a day, and then returned to his own dwelling. He was kept under surveillance there for nearly a month, and in the early days of July was imprisoned in La Force. He carried poison with him, but never used it. His tender affection for his relatives abundantly appears from his correspondence, along with his profound attachment to the great ideas of the Revolution and his noble love of country. On one of the walls of the Carmelite convent to which for a short time the prisoners were removed Vergniaud wrote in letters of blood: "Potius mori quam foedari." Early in October the Convention brought forward its indictment of the twenty-two Girondists. They were sent for trial to the Revolutionary tribunal, before which they appeared on the 27th of October. The procedure was a travesty of justice. Early on the morning of the 31st of October 1793 the Girondists were conveyed to the scaffold, singing on the way the Marseillaise and keeping up the strain till one by one they were guillotined. Vergniaud was executed last. He died unconfessed, a philosopher and a patriot.

See Gay de Vernon, *Vergniaud* (Limoges, 1858); and L. de Verdière, *Biographie de Vergniaud* (Paris, 1866). (T. S.)

VERHAEREN, ÉMILE (1855–), Belgian poet, was born at Saint-Amand, near Antwerp, on the 21st of May 1855. He was sent to school at Ghent, where he formed a friendship with Georges Rodenbach. He studied at the university of Louvain, and there started a journal, *La Semaine*, which he edited in conjunction with the operatic singer Van Dyck. *La Semaine* was suppressed by the authorities, as was its successor, *Le Type*, in which Verhaeren had as fellow-workers Max Waller, Iwan Gilkin and Albert Giraud. In 1881 he was admitted to the bar at Brussels, but he soon devoted his whole energies to literature, and especially to the organs of "young Belgium," *La Jeune Belgique* and *L'Art moderne*, making himself especially the champion of the impressionist painters. Verhaeren learnt his art of poetry from the great Flemish artists, and in his early robust works, *Les Flamandes* (1883) and *Les Moines* (1886), he displays similar qualities of strength, sometimes degenerating into violence. A period of physical weakness followed, translated into terms of poetry in three volumes of verse, *Les Soirs* (1887), *Les Débâcles* (1888) and *Les Flambeaux noirs* (1889). *Au bord de la route* (1890) and *Les Apparus dans mes chemins* (1891) followed. Verhaeren then passed from applying his pictorial method to psychological studies to the task of individualizing the towns, villages and fields of his native country, the first outcome being his *Campagnes hallucinées* (1893). In *Villages illusoires* he describes the tragedy of the fields and farms deserted by the people in their race to the towns, and in *Les Villes tentaculaires* (1895) the great industrial centres devouring the surrounding country. Later volumes of poems are *Les Heures claires* (1896), *Les Visages de la vie* (1899), *Les Petites Légendes* (1900), *Les Forces tumultueuses* (1901); *Les Tendresses premières* (1904). In 1898 he wrote a lyric drama *Les Aubes*, in 1900 a four-act piece *Le Cloître*, represented both in Brussels and Paris, and in 1901 a historical drama *Philippe II.*

The poems of Émile Verhaeren were translated into English by Alma Strettel (1899); and *Les Aubes* by Mr Arthur Symons (1898). A long list of articles dealing with Verhaeren is to be found in *Poètes d'Aujourd'hui* (1900) of A. van Bever and Paul Léautaud.

VERKHNE-UDINSK, a town of Asiatic Russia, in East Siberia, province of Transbaikalia, on the right bank of the Uda, at its confluence with the Selenga, 102 m. by rail E. of Lake Baikal, to which steamers ply. Pop. (1883) 4130; (1897) 8002. It was founded as a small fort in 1668, and is a centre for the overland trade in tea with China, and an emporium both for grain and animal products, exported, and for metals, machinery and manufactured goods, imported. Its yearly fair is of great importance.

VERLAINE, PAUL (1844–1896), French lyric poet, was born at Metz on the 30th of March 1844. He was the son of one of Napoleon's soldiers, who had become a captain of engineers. Paul Verlaine was educated in Paris, and became clerk in an insurance company. He was a member of the Parnassian circle, with Catulle Mendès, Sully Prudhomme, François Coppée and the rest. His first volume of poems, the *Poèmes saturniens* (1866), was written under Parnassian influences, from which the *Fêtes galantes* (1869), as of a Watteau of poetry, began a delicate escape; and in *La Bonne Chanson* (1870) the defection was still more marked. He married in 1870 Mlle. Mautet. During the Commune he was involved with the authorities for having sheltered his friends, and was obliged to leave France. In 1871 the strange young poet Jean Arthur Rimbaud came somewhat troublingly into his life, into which drink had already brought a lasting disturbance. With Rimbaud he wandered over France, Belgium, England, until a pistol-shot, fortunately ill-aimed, against his companion brought upon him two years of imprisonment at Mons. Solitude, confinement and thought converted a pagan into a Catholic, without, however, rooting out what was most human in the pagan; and after many years' silence he published *Sagesse* (1881), a collection of religious poems, which, for humble and passionate conviction, as well as originality of poetic beauty, must be ranked with the finest religious poems ever written. *Romances sans paroles*, composed during the intervals of wandering, appeared in 1874, and shows us Verlaine at his most perfect moment of artistic self-possession, before he has quite found what is deepest in himself. He returned to France in 1875. His wife had obtained a divorce from him, and Verlaine made another short stay in England, acting as a teacher of French. After about two years' absence Verlaine was again in France. He acted as teacher in more than one school and even tried farming. The death of his mother, to whom he was tenderly attached, dissolved the ties that bound him to "respectable" society. During the rest of his life he lived in poverty, often in hospital, but always with the heedless and unconquerable cheerfulness of a child. After a long obscurity, famous only in the Latin Quarter, among the cafés where he spent so much of his days and nights, he enjoyed at last a European celebrity. In 1894 he paid another visit to England, this time as a distinguished poet, and lectured at London and Oxford. He died in Paris on the 8th of January 1896. His eighteen volumes of verse (among which may be further mentioned *Jadis et naguère*, 1884; *Amour*, 1888; *Parallèlement*, 1889; *Bonheur*, 1891) vary greatly in quality as in substance; they are all the sincere expression, almost the instantaneous notation, of himself, of his varying moods, sensual passion, the passion of the mystic, the delight of the sensitive artist in the fine shades of sensation. He brought into French verse a note of lyrical song, a delicacy in the evocation of sound and colour, which has seemed almost to create poetry over again, as it provides a language out of which rhetoric has been cleansed and a rhythm into which a new music has come with a new simplicity. (A. Sy.)

His *Œuvres complètes* (3 vols.) were published in 1899, &c.; *Œuvres posthumes* (1903). See also *Paul Verlaine, sa vie, son œuvre*, by E. Lepelletier (1907); monographs by M. Dullaert (Ghent, 1896), C. Morice (1888); also Anatole France, *La Vie littéraire* (3rd series, 1891); J. Lemaître, *Nos contemporains* (1889), vol. iv.; E. Delille, "The Poet Verlaine," in the *Fortnightly Review* (March 1891); A. Symons, in the *National Review* (June 1892); V. Thompson, *French Portraits* (Boston, U.S.A., 1900); and the poet's own *Confessions* (1895) and his *Poètes maudits* (1888). A bibliography of Verlaine with an account of the existing portraits of him is included in the *Poètes d'Aujourd'hui* (11th ed., 1905) of MM. A. van Bever and P. Léautaud. The *Vie* by Lepelletier has been translated into English by E. M. Lang (1909).

VERLAT, MICHEL MARIE CHARLES (1824–1890), Belgian painter, was born at Antwerp on the 25th of November 1824. He was a pupil of Nicaise de Keyser, and studied at the Antwerp Academy. In 1842 appeared his first important picture, "Pippin the Short Killing a Lion." About 1849 he went to Paris, where he worked under Ary Scheffer. In 1855 he won a gold medal at the Exposition Universelle at Paris with his "Tiger Attacking a Herd of Buffaloes," and in 1858 exhibited "Le Coup de collier" (now in the Antwerp Gallery) at the Paris Salon. In 1866 he was appointed director of the Academy at Weimar, where he painted some fine portraits, notably those of the grand-duchess of Saxony and of the musician Liszt. Soon after his return to Antwerp in 1875 he visited Palestine, and brought back a large number of interesting pictures, including "Vox Populi" (Antwerp Gallery), "The Tomb of Jesus," and "The Flight into Egypt." In 1885 he was appointed director of the Antwerp Academy. Other important works by Verlat are the panoramas of the battle of Waterloo and the treaty of San Stefano, "Christ between the Two Thieves," "Defending the Flock" (Antwerp Gallery), "Oxen Ploughing in Palestine" (Antwerp Gallery), "Godfrey of Bouillon at the Siege of Jerusalem" (Brussels Gallery), and "Sheep-Dog Defending the Flock" (Brussels Gallery). He executed a series of original etchings, and published in 1879 a book on the Antwerp Academy. He died at Antwerp on the 23rd of October 1890.

VERMANDOIS, a French countship composed originally of the two burgraviates (châtellenies) of St Quentin (Aisne) and Péronne (Somme). Herbert I., the earliest of its hereditary counts, was descended in direct male line from the emperor Charlemagne, and was killed in 902 by an assassin in the pay of Baldwin II., count of Flanders. His son, Herbert II. (902–943), a man absolutely devoid of scruples, considerably increased the territorial power of the house of Vermandois, and kept the lawful king of France, the unlucky Charles the Simple, prisoner for six years. His successors, Albert I., Herbert III., Albert II., Otto and Herbert IV., were unimportant. In 1077 the last male of the first house of Vermandois, Herbert IV., received the countship of Valois in right of his wife. He died soon afterwards, leaving his inheritance to his daughter Adela, whose first husband was Hugh the Great, the brother of king Philip I. Hugh was one of the leaders of the first crusade, and died in 1102 at Tarsus in Cilicia. The eldest son of Hugh and Adela was count Raoul (Rudolph) I. (*c.* 1120–1152), who married Alix of Guyenne, sister of the queen, Eleanor, and had by her three children: Raoul (Rudolph) II., the Leper (count from 1152–67); Isabelle, who possessed from 1167 to 1183 the countships of Vermandois, Valois and Amiens conjointly with her husband, Philip of Alsace, count of Flanders; and Eleanor. By the terms of a treaty concluded in 1185 with the king, Philip Augustus, the count of Flanders kept the countship of Vermandois until his death, in 1191. At this date a new arrangement gave Eleanor (d. 1213) a life interest in the eastern part of Vermandois, together with the title of countess of St Quentin, and the king entered immediately into possession of Péronne and its dependencies.

See Anselme, *Histoire généalogique de la maison royale de France* (1726), i. 48–51 and 531–34; Colliette, *Mémoires pour l'histoire du Vermandois* (1771–72). (A. Lo.)

VERMICELLI (plural of Ital. *vermicello*, little worm, Lat. *vermicellus*, diminutive of *vermis*, worm), the name of a kind of paste, made of the granular meal of certain hard wheats, and used as a food. It is made into worm-like threads, whence its name, and differs from macaroni only in being made solid and not in hollow tubes. "Spaghetti" (dim. of *spago*, a small cord) is a larger kind of vermicelli. In Italy these various pastes form a staple article of food. In other countries "vermicelli" is used in soups and puddings, &c.

VERMIGLI, PIETRO MARTIRE, generally known as PETER MARTYR (1500–1562), born at Florence on the 8th of May 1500, was son of Stefano Vermigli, a follower of Savonarola, by his first wife, Maria Fumantina. He owed his Christian names to a vow which his father, actuated by the death of several children in infancy, had made to dedicate any that survived to the Dominican saint, Peter Martyr, who lived in the 13th century. Educated in the Augustinian cloister at Fiesole, he was transferred in 1519 to the convent of St John of Verdara near Padua, where he graduated D.D. about 1527 and made the acquaintance of the future Cardinal Pole. From that year onwards he was employed as a public preacher at Brescia, Pisa, Venice and Rome; and in his intervals of leisure he mastered Greek and Hebrew. In 1530 he was elected abbot of the Augustinian monastery at Spoleto, and in 1533 prior of the convent of St Peter *ad Aram* at Naples. About this time he read Bucer's commentaries on the Gospels and the Psalms and also Zwingli's *De vera et falsa religione*; and his Biblical studies began to affect his views. He was accused of erroneous doctrine, and the Spanish viceroy of Naples prohibited his preaching. The prohibition was removed on appeal to Rome, but in 1541 Vermigli was transferred to Lucca, where he again fell under suspicion. Summoned to appear before a chapter of his order at Genoa, he fled in 1542 to Pisa and thence to another Italian reformer, Bernardino Ochino, at Florence. Ochino escaped to Geneva, and Vermigli to Zürich, thence to Basel, and finally to Strassburg, where, with Bucer's support, he was appointed professor of theology and married his first wife, Catherine Dammartin of Metz.

Vermigli and Ochino were both invited to England by Cranmer in 1547, and given a pension of forty marks by the government. In 1548 Vermigli was appointed regius professor of divinity at Oxford, in succession to the notorious Dr Richard Smith, and was incorporated D.D. In 1549 he took part in a great disputation on the Eucharist. He had abandoned Luther's doctrine of consubstantiation and adopted the doctrine of a Real Presence conditioned by the faith of the recipient. This was similar to the view now held by Cranmer and Ridley, but it is difficult to prove that Vermigli had any great influence in the modifications of the Book of Common Prayer made in 1552. He was consulted on the question, but his recommendations seem hardly distinguishable from those of Bucer, the effect of which is itself disputable. He was also appointed one of the commissioners for the reform of the canon law.

On Mary's accession Vermigli was permitted to return to Strassburg, where, after some opposition raised on the ground that he had abandoned Lutheran doctrine, he was reappointed professor of theology. He befriended a number of English exiles, but had himself in 1556 to accept an offer of the chair of Hebrew at Zürich owing to his increased alienation from Lutheranism. He was invited to Geneva in 1557, and to England again in 1561, but declined both invitations, maintaining, however, a constant correspondence with Jewel and other English prelates and reformers until his death at Zürich on the 12th of November 1562. His first wife, who died at Oxford on the 15th of February 1553, was disinterred in 1557 and tried for heresy; legal evidence was not forthcoming because witnesses had not understood her tongue; and instead of the corpse being burnt, it was merely cast on a dunghill in the stable of the dean of Christ Church. The remains were identified after Elizabeth's accession, mingled with the supposed relics of St Frideswide to prevent future desecration, and reburied in the cathedral. Vermigli's second wife, Caterina Merenda, whom he married at Zürich, survived him, marrying a merchant of Locarno.

Vermigli published over a score of theological works, chiefly Biblical commentaries and treatises on the Eucharist. His learning was greater than his originality, and he was one of the least heterodox of the Italian divines who rejected Roman Catholicism. His views approximated most nearly to those of Martin Bucer.

Josias Simler's *Oratio*, published in 1563 and translated into English in 1583, is the basis of subsequent accounts of Vermigli. The best lives are by F. C. Schlosser (1809) and C. Schmidt (1858). See also Parker Soc. Publ. (General Index), especially the Zürich Letters; Strype's Works; Foxe's *Acts and Monuments*; Burnet's *Hist.*, ed. Pocock; Dixon's *History*; and *Dict. of Nat. Biogr.* lviii. 253–256. (A. F. P.)

VERMILION, a scarlet pigment composed of mercuric sulphide, HgS. It may be obtained direct from pure and bright coloured portions of the native ore cinnabar, or, artificially, by subliming a mixture of mercury and sulphur. The product is ground and levigated; and when dry it is ready for use. It is also prepared by digesting precipitated mercuric sulphide with an alkaline sulphide for some hours; it is said that Chinese vermilion owes its superiority to being made in this way. In addition to its brilliance, vermilion is a pigment of great intensity and durability, remaining unaffected by acid fumes. Being costly, it is much subject to adulteration; but the fraudulent additions may easily be detected by volatilization, which in the case of pure vermilion leaves no residue. See PIGMENTS and MERCURY.

VERMIN (Fr. *vermine*, formed as if from Lat. *verminus*, *vermis*, a worm), the collective name applied to various classes of objectionable, harmful or destructive animals. To gamekeepers and those interested in the preservation of game, all animals such as the pole-cat, weasel, stoat, hawks, owls, &c., which destroy the eggs or young of preserved birds, are classed as "vermin," and the same term includes rats, mice, &c. It is also the collective name given to all those disgusting and objectionable insects that infest human beings, houses, &c., when allowed to be in a filthy and unsanitary condition, such as bugs, fleas, lice, &c.

VERMONT, a North Atlantic state of the United States of America and one of the New England group, lying between latitude 42° 44′ and 45° 0′ 43″ N., and between longitudes 3° 35′ and 5° 29′ E. from Washington. It is bounded N. by the Canadian province of Quebec, E. by the Connecticut river, which separates it from New Hampshire, S. by Massachusetts, and W. by New York and Lake Champlain, which separates it in part from New York. Its total area is 9564 sq. m., and of this 440 sq. m. is water surface.

Surface.—Vermont is a portion of the plateau-like New England upland, broken by mountain ranges, individual mountains and high hills, rising above the general upland surface, and by deep narrow valleys, cut below that surface. The mean elevation of the state above the sea is about 1000 ft. Extremes range from 106 ft. at Maquam on the N.E. shore of Lake Champlain (96 ft.) to 4364 ft. at the summit of Mount Mansfield, about 25 m. E. of that lake. The most prominent feature of the surface is the Green Mountains, which extend nearly N. and S. through the state a little W. of the middle. From the Massachusetts border N. for two-thirds the length of the state the range is only slightly broken, but farther N. it is cut deep by the valleys of the Winooski and Lamoille rivers. The crest line is generally more than 2000 ft. high, considerable areas are above 2500 ft., and the following summits exceed 4000 ft.: Mount Mansfield, 4364 ft.; Killington Peak, 4241 ft.; Camel's Hump, 4088 ft.; Mount Lincoln, 4078 ft.; and Jay Peak, 4018 ft. West of the Green Mountains the Taconic Mountains form a nearly parallel (but distinct) range, extending from New York and Massachusetts N. nearly to the centre of Vermont; and a series of broken uplifts, known as the Red Sandrock Mountains, extend farther N. along the shore of Lake Champlain. The Taconic Mountains rise in very irregular masses to 1500–2000 ft., and reach their maximum elevation in Mount Equinox at 3816 ft. The Red Sandrock Mountains are similar to one another in form and structure, generally rounded on the N. and E., but with some rugged escarpments facing the lake; their highest point is Snake Mountain (1271 ft.) in Addison county. There are no mountain ranges in the state E. of the Green Mountains, but distributed along the entire E. border are a number of tall and oval or conical shaped masses known as the Granitic Mountains, and between these and the Green Mountains the country is largely occupied by high hills and deeply carved valleys. Mount Ascutney, one of the Granitic Mountains, rises abruptly from the floor of the Connecticut Valley to a height of 3320 ft. The least broken section of Vermont is on the somewhat gentle slope of the Green Mountains in the N.W. and on Grand Isle, North Hero Island, and Isle La Motte in Lake Champlain. The forms of Vermont's mountains, even to the highest summits, were to a great extent rounded by glaciation, but as the rocks vary much in texture and are often steeply inclined, stream erosion has cut valleys deep and narrow, often mere gorges.

Where the Green Mountain range is unbroken, in the S. two-thirds of the state, it forms a water-parting between the streams which flow W. or N.W. into Lake Champlain or the Hudson river and those flowing S.E. into the Connecticut river; but farther N. the line separating the Hudson-Champlain basin from the Connecticut basin runs among the Granitic Mountains; and extending 25 m. S. from the Canadian border is a small area that is drained N. into Lake Memphremagog, the waters of which, like those of Lake Champlain, are tributary to the St Lawrence river. North of Massachusetts the Connecticut river is wholly within New Hampshire—Vermont's eastern boundary is low-water mark on the W. bank of the Connecticut river. The largest and only navigable rivers of Vermont are among those flowing into Lake Champlain: the Missisquoi, the Lamoille, the Winooski and Otter Creek. The Batten Kill is the principal river flowing into the Hudson. The Deerfield, West, Williams, White, Passumpsic and Nulhegan rivers are the largest of the many streams which are tributary to the Connecticut. The Black, Barton and Clyde rivers flow into Lake Memphremagog. Vermont's rivers are generally swift, and in many places they are made very picturesque by their clear and sparkling waters, rapids, falls, gorges and wooded banks.

Lake Champlain, which lies beautifully in the valley between the Green and Adirondack mountains, belongs mostly to Vermont. The state has a shore line upon it of 150 m. or more, and in its N. portion are numerous islands which are attractive resorts during the summer season. On the N. border of the state is Lake Memphremagog with islands, a rugged prominence known as Owl's Head on its W. border, Jay Peak, farther back, and a beautiful farming country to the eastward. There are also a large number of small lakes and ponds lying wholly within the state. Of these Lake Bomoseen in Rutland county and Willoughby Lake in Orleans county are the largest. Willoughby Lake is about 6 m. long by 1–1½ m. wide, and its situation between two rugged mountains makes a scene of great natural beauty. All the lakes of the state were formed by glaciation.

Fauna.—The most common wild animals are deer, rabbits, squirrels, raccoons, skunks, woodchucks and muskrats. There are some porcupines, red foxes, minks and martens, but the moose, wolf and lynx are practically extinct. The ruffed grouse (or "partridge") is the most common of game birds, but woodcock, ducks and geese are quite common. Prominent among a great variety of song-birds and insectivorous birds are the robin, blue bird, cat bird, sparrows, meadow-lark, bobolink, thrushes, chickadee, wrens, brown thrasher, gold finch, cedar wax-wing, flycatchers, nuthatches, flicker (golden-winged woodpecker), downy and hairy woodpeckers, rose-breasted grosbeak, Baltimore oriole, barn-swallow, chimney swift, purple martin, purple finch (linnet), vireos and several species of warblers. Birds of prey comprise several species of hawks and owls, and a few eagles. A few sturgeon are taken in Lake Champlain. The lakes, ponds and streams afford some of the best trout fishing in the country, and many of them also abound in pickerel, pike, perch, black bass and land-locked salmon. There is a state fish and game commissioner, and the state has a fish hatchery at Roxbury and a forest and game farm at Sharon. There are Federal hatcheries at Swanton (for pike perch and yellow perch) and at Holden (for trout).

Flora.—Vermont (*vert mont*), the Green Mountain State, was so named from the evergreen forests of its mountains, whose principal trees are spruce and fir on the upper slopes and white pine and hemlock on the lower. Among deciduous trees the state is noted for its sugar maples; birch and beech are common on the hills, and oaks, elm, hickory, ash, poplar, basswood, willow, chestnut and butternut on the less elevated areas. Among indigenous fruit-bearing trees, shrubs, vines and plants are the plum, cherry, grape, blackberry, raspberry, cranberry and strawberry. A few of the medicinal plants are ginseng, pleurisy root, snake root, blood root, blue flag and marshmallow. Orchids are very prominent among a great variety of flowering plants. Along the shore of Lake Champlain are a few species of maritime plants that remain from the time when portions of western Vermont were covered by the sea, and on the upper slopes of some of the higher mountains are a few Alpine species; these, however, are much less numerous on the Green Mountains of Vermont than on the White Mountains of New Hampshire. The state's lumber trade was important until 1890, when the white pine was nearly exhausted, although there were still spruce and hemlock.

Climate.—The state usually has long and severe winters and cool summers, but sudden changes of temperature are common at all seasons. The mean temperature for January, the coldest month, is only 17° F.; for the three winter months it is 19° F., and for the five months from November to March inclusive it is 24·3° F. For July, the warmest month, the mean temperature is 68° F.; for the entire year it is 43° F. Extremes of temperature have ranged from -36° F. at Woodstock, Windsor county, in February 1896 to 97° F. at Cornwall, Addison county, in June 1901. The eastern section of the state is colder than the western, and the central or most mountainous section is still colder; for example, the mean annual temperature of Burlington, on Lake Champlain, is 46° F., while that of Saint Johnsbury, a little farther S. and near the E. border, is only 42° F., and that of Northfield, still farther S. but in the middle section, is only 41° F. The mean annual precipitation for the entire state is about 38·5 in.; more rain falls in summer than in any other season, and more falls in the southern section than in the northern. The average annual fall of snow throughout the state is about 90 in., but at Jacksonville near the S. border it often exceeds 110 in. More snow falls in February than in any other month. In the Connecticut and Hudson-Champlain valleys the winds blow mostly from either the N. or the S., but in several of the smaller valleys the prevailing winds are from the N.W.

Soil.—The soil is for the most part glacial drift, composed of clay, sand and gravel, and varying greatly in depth. On the higher elevations it is generally stony and sterile, but in the valleys and on many of the lower hills, where it consists largely of clay and sand, it is quite productive. The best soils are in the west section, where limestone clays or shell marls are common.

Forests.—Vermont was heavily forested with white pine, spruce and hemlock, and, in the southern part of the state and along the shore of Lake Champlain, with some hard woods. The white pine had been much cut off by 1890 and it is no longer commercially important. The woodland area of the state in 1900 was estimated to be 3900 sq. m., about 43% of the land area of the state.

Fisheries.—Lake Champlain furnishes the only commerical fishing grounds in Vermont, with the exceptions of small catches of white fish in Lake Bomoseen, Lake St Catherine in Rutland county and Lake Memphremagog. The total catch in 1895 was 208,139 lb, valued at $7160, and in 1902 was 528,682 lb, valued at $37,669. The capital invested in fisheries in 1902 was $9417, and the number of men employed, 145. The most valuable fish taken was wall-eyed pike, and the catch of this fish and of pickerel from Lake Champlain in 1902 exceeded in value that from any other body of fresh water in the United States excepting Lake Huron and Lake Erie. The wall-eyed pike taken in 1902 were valued at $16,915 (210,936 lb); white fish, $5777 (80,191 lb); pickerel, $4144 (51,711 lb); yellow perch, $2575 (43,917 lb); sturgeon, $2051 (15,590 lb), and suckers, $1854 (37,375 lb); other varieties taken in smaller quantities included smelt, sun-fish and eels.

Agriculture.—Vermont is largely an agricultural state: in 1900, out of a total of 134,933 persons engaged in gainful occupations, 49,820 were engaged in agriculture, 36,180 in manufacturing and mechanical pursuits, 23,028 in domestic and personal service, 18,889 in trade and transportation, and 7016 in professional service; and of a total land area of 9124 sq. m., 7382 sq. m. (4,724,400 acres) were included in farms. The percentage of improved farm land, as in Maine, New York and Pennsylvania, increased from 1850 until 1890 and decreased after 1890; and in 1900 out of a total acreage of 4,724,400 acres only 2,126,624 acres (45%) were improved. Of the 33,104 farms in the state in 1900, 25,982 were farmed by their owners, 1373 by part owners, 314 by owners and tenants, 2424 by cash tenants, 2396 by share tenants, and 615 by managers; 637 farms had more than 500 acres, 3431 were between 260 and 500 acres, 5512 between 175 and 260 acres, 10,215 between 100 and 175 acres, 6513 between 50 and 100 acres, 3511 between 20 and 50 acres, and 3285 less than 20 acres; and dairy produce was the principal source of income of more than one-half of these (16,700), live stock the principal source of income of 7323 farms, and hay and grain of 2519 farms. The general sterility of the soil except along rivers and the bases of hills has made intensive cultivation always necessary, and the competition of new and rich western farm lands has made the agriculture of Vermont develop further toward specialization in dairying and raising live stock. In 1910 there were 495,000 neat cattle (285,000 milch cows), 94,000 horses (average value, $106), 229,600 sheep and 95,000 swine. The horses of Vermont have been famous in the development of American racing stocks; the Morgan stock is best known, and other famous Vermont strains are Messenger and Black Hawk. Hay and forage are the most important crops, and Vermont grasses for grazing have been favourably known since the close of the 18th century. In 1909 on 879,000 acres a crop of hay (excluding forage) was raised valued at $16,155,000. The cereals are relatively unimportant. The largest cereal crop is oats, of which, in 1909, 2,608,000 bushels (valued at $1,304,000) were produced on 81,000 acres.

Mines and Quarries.—The principal mineral resource of Vermont is its building and monumental stone, including marble and granite and a small amount of limestone. The value of the total amount of stone produced in 1908 in Vermont was $7,152,624. Vermont marble is the best and most plentiful in the United States. It has been quarried since 1785; marble monuments were first manufactured about 1808; and at South Dorset in 1818 marble seems first to have been sawed in blocks, the earlier method having been chiselling. It is found generally throughout the western part of the state. The principal supply is in West Rutland, Proctor and Pittsford; this, the "Rutland marble," is a duller, less lustrous white, and of a greater durability than the Carrara marble, and is used largely for monuments and statuary. There are other large quarries at Dorset and East Dorset, Bennington county; the finest marbles from this region are the white, slightly marked with pale brown and with greenish lines; they are commonly used for building, the Harvard Medical School and the office of the U.S. Senate being examples. At Rutland, Proctor and Dorset many darker shades are found, including "moss vein," olive green and various shades of blue, green, yellow and pink, which are used for ornamental purposes. There are important quarries in Franklin county (at Swanton), the stone being a dark Chazy limestone, in which pink and red ("jasper," "lyonnaise" and "royal red") marbles of Cambrian age are found. At Monkton, Addison county, there is a quarry from which other red marbles are taken; and at Roxbury, Washington county, a fine serpentine, called "green marble," or verde antique, is quarried. On Isle La Motte, Grand Isle county, there are marble quarries, the characteristic colours of the marble being "Fisk black" and "Fisk grey." The output of marble in 1908 was valued at $4,679,960 (out of a total of $7,733,920 for the entire production of marble in the United States). Only less important and only less early to be established in Vermont was the quarrying of granite, which began in 1812, but which has been developed chiefly since 1880, largely by means of the building of "granite railroads" which connect each quarry with a main railway line—a means of transportation as important as the logging railways of the Western states and of Canada. The largest granite quarries are near Barre, Washington county, a city which owes its importance to the quarries. The Barre granites, like those of Woodbury and Calais (also in Washington county) and part of those of South Ryegate, Kirby and Newark (Caledonia county), are of the biotite type; they are grey, except the stone from Newark, which is pinkish. Of the quartz-monzonite type are the whitish granites of Bethel and Rochester (Windsor county) and Randolph (Orange county), the light grey of Dummerston (Windham county), and the darker greys of Cabot (Washington county), Derby (Orleans county), Hardwick and Groton (Caledonia county) and Topsham (Orange county). The olive green syenite found on Mount Ascutney, near the Connecticut river, in Windsor county, is a hornblende-augite. Other important granite quarries are near Williamstown, Dummerston, Berlin and Woodbury. The total value of the output of granite in the state in 1908 was $2,451,933. In 1908 the output of limestone was valued at $20,731; there are limestone quarries in Washington and Orange counties and on Isle La Motte. Slate-quarrying and cutting is carried on in the south-western part of the state, in Rutland county; there are important quarries at Fair Haven, Poultney, Castleton, Wells and Pawlet. In Washington county there are quarries near Northfield. The industry began about 1840, though one quarry had been opened as early as 1805. There are two green varieties, called in the trade "sea-green" and "unfading green," the former being used for a cheap roofing slate; and there are purplish varieties. In 1908 the value of slate produced was $1,710,491 (out of a total production for the United States of $6,316,817).

Manufactures.—The first important industry of the state was "rafting" lumber from Vermont through Lake Champlain and the Richelieu and St Lawrence rivers to Quebec. Burlington became a great lumber market for a trade moving in the direction of Boston after the Richelieu river was blocked to navigation and railway transportation began, and in 1882 Burlington was the third lumber centre in the United States. Mountain streams furnish important water-power, and the typical factory of Vermont has long been a sawmill run by a water-wheel. The value of sawmill products in 1905 was $5,888,441, and of planing-mill products $3,080,117. Closely connected with the manufacture of lumber is the making of paper and wood pulp, centralized at Bellows Falls, with water-power on the Connecticut river and with the raw materials near; the product was valued in 1905 at $3,831,448. Dairy industries have rapidly increased in value: in 1905 the value of butter and cheese was $6,416,434, more than any other single industry under the census classification. If a less arbitrary classification be followed the principal manufacturing industries would be stone manufacture and textiles. The first marble quarry was opened in Dorset in 1785 and a second at Middlebury in 1805; and the first granite was quarried in 1812. Barre is the centre of the granite business, and the region about Rutland, especially Proctor, is the principal seat of the marble industry. The product of stone manufactures in 1905 was $9,570,436. Vermont was almost the last of the New England states to develop textile manufactures, though the manufacture of woollen goods was begun in 1824. The greatest development was between 1900 and 1905; the total value of textiles in the former year was $5,407,217 (woollen goods, $2,572,646; hosiery and knit goods, $1,834,685; cotton goods, $999,886) and in the latter was $7,773,612 (woollen goods, $4,698,405; hosiery and knit goods, $1,988,685; and cotton goods, $1,086,522). Other important manufactures are: flour and grist mill products, foundry and machine-shop products, furniture, patent medicines and compounds, roofing materials, and scales and balances, manufactured especially at St Johnsbury.

Transportation and Commerce.—Railway transportation is supplied to Vermont by parallel lines crossing diagonally every part of the state at about equal intervals and running in general in a N.W. and S.E. direction, and by lines running N. and S. respectively along the eastern and western borders of the state. The railway map of the state thus has roughly the appearance of a gridiron. The principal railways are: the lines operated by the Boston & Maine system, extending along the eastern border from Brattleboro through Bellows Falls, and St Johnsbury to the Canada boundary (Vermont Valley, Sullivan County, and Connecticut & Passumpsic Rivers railways), with a line, the St Johnsbury & Lake Champlain railway, extending across the northern part of the state from Lunenburg to Maguam Bay; the Central Vermont railway (Grand Trunk system) which crosses the state diagonally from S.E. to N.W., connecting Burlington, Montpelier and St Albans and affording connexion to the north with Montreal and to the south over trackage shared with the Boston & Maine, with the New London Northern which is leased by this road, and the Rutland railway (New York Central system) extending along the western edge of the state and connecting Rutland with Burlington to the north and with Bellows Falls and Bennington to the south. These railways provide outlets for through freight and passenger traffic southward to Boston and New York, and to the north to St Johns and Montreal.

The southern part of the state was early opened to railways, the Sullivan County railway (operated by the Boston & Maine) having been opened in 1849; and in 1850 the state had 290 m. of railway; in 1870, 614 m.; in 1890, 991·42 m.; and on the 1st of January 1909, 1093·43 m. Water communication is afforded by Lake Champlain to the south, for seven months of the year, by way of the Champlain canal, via Whitehall, New York, to Troy and the Hudson river and the Atlantic coast, and to the north by way of the Richelieu river and the Chambly canal to the St Lawrence. The commerce of the lake consists principally of coal, wood pulp and building material, besides general merchandise. The only river with traffic of commercial importance is Otter Creek, flowing northwards into the southern part of Lake Champlain and having a navigable length of 8 m. to Vergennes, with a depth to this point of 8 ft. at low water. The commerce on Lake Champlain is carried on chiefly through Burlington, the port of entry for the Vermont customs district. The tonnage of the commerce of this port amounted, according to the reports of the United States army engineers, to 107,421 tons in 1904 and to 249,174 tons in 1908, of which in the latter year nearly 80% was lumber.

Population.—The population of Vermont in 1890 was 332,422; in 1900, 343,641; and in 1910, 355,956.[1] Of the total population in 1900, 298, 077 were native whites, 44,747 were foreign-born, 826 were negroes and 39 were Chinese. Of the inhabitants born in the United States, 19,974 were natives of New York, 9675 were natives of New Hampshire and 9111 were natives of Massachusetts. Of the foreign-born, 14,924 were French Canadians, 10,616 were English Canadians and 7453 were Irish. Of the total population, 117,344 were of foreign parentage (*i.e.* either one or both parents were foreign-born) and 27,226 were of French Canadian and 20,228 of Irish parentage, both on the father's and on the mother's side. Of 147,223 communicants of all churches in 1906, the largest number, 82,272, were Roman Catholics, 22,109 were Congregationalists, 17,471 Methodist Episcopalians, 8450 Baptists, 1501 Free Baptists and 5278 Protestant Episcopalians. The principal cities are Burlington, Rutland, Barre, Montpelier (the capital) and St Albans.

Administration.—Vermont has been governed under the constitution of 1777, that of 1786 and that of 1793, with twenty-eight amendments, of which the first was adopted in 1828, the second to thirteenth in 1836, the fourteenth to twenty-third in 1850, the twenty-fourth, twenty-fifth and twenty-sixth in 1870, and the twenty-seventh and twenty-eighth in 1883. The administrative officers of the state are a governor, a lieutenant-governor, a secretary of state, a state treasurer, and an auditor of accounts, elected by popular vote, and an inspector of finance, a commissioner of taxes, a superintendent of education, a fish and game commissioner, three railroad commissioners, and various boards and commissions, of whom some are elected by the General Assembly and some are appointed by the governor with the advice and consent of the Senate. All elections and appointments are biennial. The governor has limited powers of appointment and pardon and a veto power which may be overridden by a majority vote in each house.

The legislative department consists of a senate of 30 members, apportioned among the counties according to population, but with the proviso that each county must have at least one senator, and a House of Representatives of 245 members, one from each township. Since 1870 elections and legislative sessions have been biennial. The powers of the two houses are equal except that revenue measures must originate in the House of Representatives.

The judiciary is composed of a supreme court of seven members, a court of chancery, a county court in each county, a probate court in each probate district, and justices of the peace. The judges of the supreme court are elected biennially by the General Assembly, and all the other judicial officers are elected by the people. Sessions of the supreme court are held in each county once a year in addition to the general session which meets at some central place selected by the judges. The court of chancery is held by the judges of the supreme court, the county by a supreme court judge with the aid of two associates elected by the people of the county.

For the administration of local affairs the state is divided into 14 counties and 245 townships. There is no special board of commissioners or supervisors as in most of the other states, the county authority being the assistant judges of the county court. The assistant judges, the sheriff and the state's attorney are elected annually by popular vote. The county treasurer is elected by the assistant judges. The more important township officials are a moderator, a board of selectmen, a clerk, a treasurer and a superintendent of schools. Any community containing thirty or more houses may, with the approval of the selectmen of the town, receive a separate village organization. Their officials are a clerk, five trustees, a collector of taxes and a treasurer.

All citizens of the United States residing in Vermont are citizens of the state. The right of suffrage is confined by the constitution to adult male citizens who have resided in the state for one year. Women have the right to vote in all elections relating to schools and school officers in cities, towns and graded school districts, and also the right to be elected to any local school position or to the office of township clerk. The original method of revising the constitution was adopted from Pennsylvania (see *History*), and it was retained long after Pennsylvania had abandoned it. Thirteen censors chosen septennially were empowered to suggest amendments and to call a convention to pass upon them. The censors, being elected on a general ticket, were always more progressive than the convention, which was chosen on the principle of equal township representation. In spite of the repeated recommendations of the censors, the convention refused to abolish the collegiate executive and the unicameral legislative system until 1836. Propositions to establish the judiciary on a more permanent tenure were also voted down in 1814, 1822, 1857 and 1870, and the state still elects its judges for two years' terms. On its own suggestion, the council of censors was abolished in 1870 and the present method of amending the constitution was adopted. Every tenth year, beginning in 1880, the Senate is authorized to propose amendments, which proposals, if concurred in by the majority of the members of the House of Representatives, are published in the principal newspapers of the state. If they are again approved by a majority of each house in the next General Assembly, they are submitted finally to a direct popular vote, a majority of the votes cast being decisive.

Miscellaneous Laws.—A married woman may hold her separate property, carry on business, sue and be sued the same as if she

[1] According to previous censuses, the population was as follows: (1790) 85,425; (1800) 154,465; (1810) 217,895; (1820) 235,981; (1830) 280,652; (1840) 291,948; (1850) 314,120; (1860) 315,098; (1870) 330,551; (1880) 332,286. The increase between 1850 and 1900 was remarkably small.

were single, except that in conveying or mortgaging her real estate she must be joined by her husband. A widow has a dower interest in one-third of her husband's real estate unless barred by a jointure or an agreement. A widower is in any case entitled by courtesy to one-third of his wife's real estate, and he may choose between his rights by courtesy and the provisions of his wife's will. Where there is no issue and the deceased dies intestate the surviving spouse is entitled to the whole estate, both real and personal, if it does not exceed $2000, and if it exceeds that sum the survivor is entitled to $2000 and one-half of the remainder; if there are no kindred, the whole of the estate goes to the surviving spouse. The causes for a divorce are adultery, sentence to confinement in the state prison for three years or more and actual confinement at the time of the suit, intolerable severity, wilful desertion for three consecutive years or absence for seven years without being heard from, or wanton and cruel refusal or neglect of the husband to provide a suitable maintenance for his wife. The plaintiff must have resided in the state for at least the year preceding the application, and if the cause accrued in some other state or country before the parties lived together in Vermont and while neither party lived there, the plaintiff must have been a resident at least for two years preceding the action. When a divorce is granted, the defendant is not permitted to marry other than the plaintiff for three years, unless the plaintiff dies. The homestead of a householder or head of a family to the value of $500 is, so long as it continues to be used as the homestead, exempt from levy or attachment other than upon causes existing at the time it was acquired and for taxes. If the owner is a married man, he cannot sell or mortgage it, except for the purchase money, unless his wife joins him in the execution.

Education.—The public-school system is under the supervision of a state superintendent of education, elected biennially by the General Assembly, and local schools are under union superintendents and in a few cases under town superintendents. The district system was displaced in 1893 by a township system. The revenues for educational purposes are derived mainly from a state tax of 8% on the general list, from local taxes, and from the interest on the permanent school fund, which (including the money paid to Vermont by the United States government when a portion of the treasury surplus was distributed among the states in 1837) amounted in 1908 to $1,120,218. The schools are open to all children between the ages of 5 and 20, and attendance for twenty-six weeks in each year is made compulsory for those who are between the ages of 8 and 15. The average number of weeks in the "legal schools" (about 95% of the public schools) was 32 weeks in 1907–1908. The chief institutions for higher instruction are the university of Vermont and State Agricultural College (1800, 1865), a land-grant college at Burlington, Middlebury College (1800) at Middlebury, Norwich University (1819) at Northfield, and the state normal schools at Randolph (1867), Johnson (1867) and Castleton (1868).

Charitable and Penal Institutions.—The charitable and penal institutions of the state are controlled by separate boards of directors, but all are subject to the general supervision of a board of visitors composed of the governor, lieutenant-governor and speaker of the House of Representatives, and a woman appointed by the governor. There are a state prison at Windsor (1808), a house of correction at Rutland (1878), an industrial school at Vergennes (1866), and hospitals for the insane at Brattleboro (1836) and Waterbury (1891). Biennial appropriations are made for the support of the deaf and dumb, the blind and imbecile children at various institutions in Massachusetts and Connecticut.

Finance.—The chief sources of revenue for the state are a corporation tax, a collateral inheritance tax (1904) and a licence tax. There is no general property tax except a special levy of 8% on the general list for school purposes and 5% for the construction of roads. For the year ending on the 30th of June 1908 the total receipts were $1,822,390, the expenditures were $1,871,166. The state is practically free from debt, the only obligation of this character being $135,500 in 6% bonds, payable in 1910, which were issued in behalf of the Agricultural College. The banking institutions are supervised by an inspector of finance, who reports annually to the General Assembly. There were no banks in the state until 1806, when a state bank (controlled by the state) was established which was finally closed up in 1845, although as early as 1812 a law was passed to close it. The first private state bank was opened in 1817; an act of 1831 provided for a safety fund guaranteeing bank circulations and derived from a 4½% tax on capital stock and a 10% tax on profits; but this law was modified in 1842, the tax being removed from banks giving specie guarantees; and a free banking act was passed in 1851. Owing to the high rate of taxation on deposits, a considerable part of the savings of the people is sent into other states.

History.—Samuel de Champlain, as governor of Quebec, entered what is now Vermont in July 1609 in an expedition against the Iroquois, and thus laid the basis for the French claim. In 1665 the French built a fort on Isle la Motte. The first English settlement was probably made at Chimney Point, in Addison township, in 1690 by a party from Albany. The first permanent white settlement was established by Massachusetts at Fort Dummer (near the present Dummer, in the south-eastern part of the present town of Brattleboro) in 1724. Similar outposts were located during the next few years at Sartwell's Fort and Bridgman's Fort in the township of Vernon (Windham county) and at Fort Hill in the township of Putney (N. of Brattleboro, in Windham county). The territory in which these settlements had been made was involved in the boundary dispute between Massachusetts and New Hampshire, which was settled in 1741 by a decision of the king in council favourable to New Hampshire (*q.v.*). The extension of the southern boundary line by this decision due westward until it met His Majesty's other governments gave rise, however, to a controversy with New York. New Hampshire claimed that her territory extended as far to the west as those of Massachusetts and Connecticut, whereas New York, under the charter of 1664, claimed eastward to the Connecticut river. New York protested against the Bennington grant in 1749, but the question did not become serious until the chief obstacle to settlement was removed by the conquest of Canada in 1760–61. From 1761 to 1763 Governor John Wentworth of New Hampshire issued 108 grants, and settlements were established in Brattleboro, Putney, Westminster, Halifax, Marlborough, Wilmington, New Fane, Rockingham, Townshend, Vernon (Hinsdale) and Dummerston (all in Windham county, except Vernon, which is in Cheshire county). A privy council decree recognizing the claims of New York was issued on the 20th of July 1764, and the settlers were soon afterwards ordered to surrender their patents and repurchase the land from the proper authorities at Albany. Under the leadership of Ethan Allen, Seth Warner and Remember Baker (1737–1775), they refused obedience and took up arms in defence of their rights. About the close of 1771 Colonel Allen organized a regular military force among the inhabitants of the district W. of the mountains, which came to be known as the Green Mountain Boys. The trouble was soon complicated by the conflict with the mother country. On the 13th of March 1775, a riot occurred at Westminster between the people of Cumberland county and the royal authorities, in which two of the people were killed. The Green Mountain Boys, with some help from Connecticut, captured Fort Ticonderoga on the 10th of May 1775, and took part in the Canadian expedition of 1775 under Montgomery and Schuyler. Within the state itself battles were fought at Hubbardton on the 7th of July and Bennington on the 16th of August 1777. The representatives of the towns assembled in convention at Dorset and Westminster in 1776 (Jan. 16–17, July 24–25, September 25–28, October 30), and on the 15th of January 1777 adopted a declaration of independence, assumed the name New Connecticut and appointed Dr Jonas Fay (1737–1818), Thomas Chittenden (1730–1797), Hemon Allen (1740–1788), Dr Reuben Jones and Jacob Bayley a committee to submit their proceedings to the Continental Congress. The chief adviser of the committee in Philadelphia was Dr Thomas Young, a prominent physician, who had helped to draft the Pennsylvania constitution of 1776. Young advised them to call their state Vermont, and he also sent through them a circular letter, dated the 11th of April 1777, urging the people to adopt a state constitution on the Pennsylvania model. The advice was followed. A convention met at Windsor (July 2–8, 1777), and drafted a document which contained almost all of the important provisions of the constitution of Pennsylvania, such as a unicameral legislature, a plural executive and a council of censors, which was not abolished until 1870. One important variation, however, was a clause in the bill of rights providing for the abolition of slavery, Vermont being the first state in America to take such action. The first legislature of the state met at Windsor in March 1778, and voted to admit sixteen towns east of the Connecticut river which were dissatisfied with the rule of New Hampshire. As a result, New York and New Hampshire formed a secret agreement to divide the state between themselves, the mountains to be the line of division. In this crisis the British government through General Sir Frederick Haldimand offered to recognize Vermont as a separate province and to give her very liberal terms provided she would desert the other states.

Ethan Allen (*q.v.*) and some of the other leaders seemed inclined to accept these overtures, but for various reasons, the chief of which was the general success of the American cause, the scheme was soon abandoned. The difficulties with New Hampshire were adjusted in 1782, the west bank of the Connecticut being accepted as the final boundary, but New York refused to abandon her claims until 1790. In the meantime, Vermont continued as an independent state without any recognition from Congress until its admission into the Union on the 4th of March 1791. The legislature wandered about from town to town until 1808, when the capital was permanently located at Montpelier. In presidential campaigns the state has been Federalist, 1792–1800; Democratic-Republican, 1804–1820; Adams-Republican, 1824–1828; Anti-Masonic, 1832; Whig, 1836–1852; and Republican since 1856. During the War of 1812 Vermont troops took part in the battles of Chippewa, Lundy's Lane, Lake Erie and Plattsburgh; but the only engagement in the state itself was the defence of Fort Cassin (at the mouth of Otter Creek in the N.W. corner of the present Addison county) in 1813. On the 19th of October 1864 a small band of Confederate soldiers under Lieutenant B. H. Young crossed the frontier from Canada and raided the town of St Albans. A few of the inhabitants were wounded and one was killed and about $200,000 was taken from the vaults of the local banks. St Albans was also the headquarters of an attempted Fenian invasion of Canada in 1870. Since 1815 a considerable proportion of the native stock has migrated to the W.; but the loss has been partially offset by an influx of French Canadians. The wool-growing industry has been almost entirely destroyed by the competition of Australia and the West, and the people are now engaged mainly in dairy-farming, timbering, granite- and marble-quarrying, and in keeping summer boarders.

GOVERNORS

Thomas Chittenden	1778–1789
Moses Robinson	1789–1790
Thomas Chittenden,[1] Federalist	1790–1797
Paul Brigham, acting-governor, Federalist	1797
Isaac Tichenor, Federalist	1797–1807
Israel Smith, Democratic-Republican	1807–1808
Isaac Tichenor, Federalist	1808–1809
Jonas Galusha, Democratic-Republican	1809–1813
Martin Chittenden, Federalist	1813–1815
Jonas Galusha, Democratic-Republican	1815–1820
Richard Skinner, „	1820–1823
Cornelius P. Van Ness, „	1823–1826
Ezra Butler, Adams-Clay	1826–1828
Samuel C. Crafts, Adams-Clay	1828–1831
William A. Palmer, Anti-Masonic Fusion	1831–1835
Silas H. Jennison,[2] acting-governor, Whig	1835–1836
Silas H. Jennison, Whig	1836–1841
Charles Paine, „	1841–1843
John Mattocks, „	1843–1844
William Slade, „	1844–1846
Horace Eaton, „	1846–1848
Carlos Coolidge, „	1848–1850
Charles K. Williams, „	1850–1852
Erastus Fairbanks, „	1852–1853
John S. Robinson, „	1853–1854
Stephen Royce, Republican	1854–1856
Ryland Fletcher, „	1856–1858
Hiland Hall, „	1858–1860
Erastus Fairbanks, „	1860–1861
Frederick Holbrook, „	1861–1863
J. Gregory Smith, „	1863–1865
Paul Dillingham, „	1865–1867
John B. Page, „	1867–1869
Peter T. Washburn,[3] Republican	1869–1870
George W. Hendee, acting-governor, Republican	1870
John W. Stewart, Republican	1870–1872
Julius Convers, „	1872–1874
Asahel Peck, „	1874–1876
Horace Fairbanks, „	1876–1878
Redfield Proctor, „	1878–1880
Roswell Farnham, „	1880–1882
John L. Barstow, „	1882–1884
Samuel E. Pingree, Republican	1884–1886
Ebenezer J. Ormsbee, „	1886–1888
William P. Dillingham, „	1888–1890
Carroll S. Page, „	1890–1892
Levi K. Fuller, „	1892–1894
Urban A. Woodbury, „	1894–1896
Josiah Grout, „	1896–1898
Edward C. Smith, „	1898–1900
William W. Stickney, „	1900–1902
John G. McCullough, „	1902–1904
Charles J. Bell, „	1904–1906
Fletcher D. Proctor, „	1906–1908
George H. Prouty, „	1908–1910
John A. Mead, „	1910–

[1] Died in office on the 25th of August 1797; succeeded by the lieutenant-governor.

[2] As there was no governor elected by the people, Jennison as lieutenant-governor elect acted as governor.

[3] Died in office on the 7th of February 1870; succeeded by the lieutenant-governor.

BIBLIOGRAPHY.—For physical description and material on minerals see the *Report on the Geology of Vermont: Descriptive, Theoretical, Economical and Scenographical* (2 vols., Claremont, N.H., 1861); G. H. Perkins, *Reports of the State Geologist*, especially vols. iv., v., vi., new series (Concord, N.H., 1904, 1906, 1908); and "Underground Waters of Vermont" in *Water Supply and Irrigation Paper No. 114* (Washington, 1905) of the U.S. Geological Survey; T. Nelson Dale, *The Granites of Vermont* (ibid., 1909), an abstract of which appears in the sixth volume of the state *Report* mentioned above; and Henry M. Seely, "The Geology of Vermont," pp. 53–67, vol. 5 (1901) of *The Vermonter*.

For the government of the state see *The Revised Laws of Vermont* (Rutland, 1881); the *Vermont Legislative Directory*, published biennially at Montpelier; the biennial reports of the secretary of state, the auditor, the treasurer, the commissioner of state taxes, the superintendent of education, the supervisors of the insane, &c., and the annual reports of the inspector of finance. See also L. H. Meader, *The Council of Censors* (Providence, 1899); F. A. Wood, *The History of Taxation in Vermont* (New York, 1894), and G. G. Bush, *History of Education in Vermont* (Washington, 1900).

For a general bibliography of Vermont history see M. D. Gilman, *Bibliography of Vermont* (Burlington, 1897). The standard authorities for the period before 1791 are: Ira Allen, *Natural and Political History of the State of Vermont* (London, 1898); B. H. Hall, *History of Eastern Vermont to the Close of the Eighteenth Century* (2 vols., New York, 1858, 2nd ed., Albany, 1865); and Hiland Hall, *History of Vermont from its Discovery to its Admission into the Union in 1791* (Albany, 1868). A more recent book, based almost entirely on these three, but containing a few sketchy supplementary chapters, is R. E. Robinson, *Vermont* (Boston, 1892) in the "American Commonwealths" Series. See also *Records of the Council of Safety and Governor and Council of Vermont* (8 vols., Montpelier, 1873–1880); *Vermont Historical Society, Collections* (2 vols., Montpelier, 1870–1871); *Proceedings* (1 vol., Montpelier, 1898); and *Report of the Regents of the University of New York on the Boundaries of the State of New York* (2 vols., Albany, 1874–1884).

VERMOREL, AUGUSTE JEAN MARIE (1841–1871), French journalist, was born at Denicé, France, on the 21st of June 1841. A radical and socialist, he was attached to the staff of the *Presse* (1864) and the *Liberté* (1866). In the latter year he was appointed editor of the *Courrier Français*, and his attacks on the government in that organ led to his imprisonment. In 1869 he was editor of the *Réforme*, and was again imprisoned for denouncing the government. On the overthrow of the Empire in 1870 he was released and took an active part in the Commune. He was dangerously wounded while fighting at the barricades, taken prisoner and removed to Versailles, where he died on the 20th of June 1871.

VERMOUTH, an alcoholic beverage, the basis of which consists of a fortified and aromatized white wine. The best French vermouth is made from the white wines of the Hérault district. The wine is fortified with spirit up to a strength of about 15% of alcohol, and is then stored in casks exposed to the sun's rays for a year or two. Another portion of the wine is fortified up to a strength of about 50% of alcohol, and in this various aromatic and tonic materials are macerated, in casks which are exposed to the sun in the same way as the bulk of the wine. The two liquids are then mixed in such proportions as to make the strength of the ultimate product about 17% of alcohol by volume. Excellent vermouth is also manufactured in Italy, the produce of that country being generally of a "sweet," that made in France of a "dry" type.

VERNACULAR (Lat. *verna*, dim. *vernaculus*, a slave born in his master's house), a term meaning native or indigenous, belonging to the country where a person is born. The word is practically confined in English usage to language, whether of the country as a whole or of particular dialects or idioms.

VERNE, JULES (1828–1905), French author, was born at Nantes on the 8th of February 1828. After completing his studies at the Nantes lycée, he went to Paris to study for the bar. About 1848, in conjunction with Michel Carré, he wrote librettos for two operettas, and in 1850 his verse comedy, *Les Pailles rompues*, in which Alexandre Dumas fils had some share, was produced at the Gymnase. For some years his interests alternated between the theatre and the bourse, but some travellers' stories which he wrote for the *Musée des Familles* seem to have revealed to him the true direction of his talent —the delineation, viz., of delightfully extravagant voyages and adventures to which cleverly prepared scientific and geographical details lent an air of verisimilitude. Something of the kind had been done before, after kindred methods, by Cyrano de Bergerac, by Swift and Defoe, and later by Mayne Reid. But in his own particular application of plausible scientific apparatus Verne undoubtedly struck out a department for himself in the wide literary genre of *voyages imaginaires*. His first success was obtained with *Cinq semaines en ballon*, which he wrote for Hetzel's *Magazin d'Éducation* in 1862, and thenceforward, for a quarter of a century, scarcely a year passed in which Hetzel did not publish one or more of his fantastic stories, illustrated generally by pictures of the most lurid and sensational description. The most successful of these romances include: *Voyage au centre de la terre* (1864); *De la terre à la lune* (1865); *Vingt mille lieues sous les mers* (1869); *Les Anglais au pôle nord* (1870); and *Voyage autour du monde en quatre-vingts jours*, which first appeared in *Le Temps* in 1872. The adaptation of this last (produced with immense success at the Porte St Martin theatre on the 8th of November 1874) and of another excellent tale, *Michael Strogoff* (at the Châtelet, 1880), both dramas being written in conjunction with Adolphe d'Ennery, proved the most acceptable of Verne's theatrical pieces. The novels were translated into the various European languages—and some even into Japanese and Arabic—and had an enormous success in England. But after 1877, when he published *Hector Servadac*, a romance of existence upon a comet, the writer's invention began to show signs of fatigue (his kingdom had been invaded in different directions and at different times by such writers as R. M. Ballantyne, Rider Haggard and H. G. Wells), and he even committed himself, somewhat unguardedly, to very gloomy predictions as to the future of the novel. Jules Verne's own novels, however, will certainly long continue to delight readers by reason of their sparkling style, their picturesque *verve*—apparently inherited directly from Dumas—their amusing and good-natured national caricatures, and the ingenuity with which the love element is either subordinated or completely excluded. M. Verne, who was always extremely popular in society, divided his time for the most part between Paris, his home at Amiens and his yacht. He was a member of the Legion of Honour, and several of his romances were crowned by the French Academy, but he was never enrolled among its members. He died at Amiens on the 24th of March 1905. His brother, Paul Verne, contributed to the *Transactions of the French Alpine Club*, and wrote an *Ascension du Mont Blanc* for his brother's collection of *Voyages extraordinaires* in 1874.

VERNET, the name of three eminent French painters.

I. Claude Joseph Vernet (1714–1789), who was born at Avignon on the 14th of August 1714, when only fourteen years of age aided his father, a skilful decorative painter, in the most important parts of his work. But the panels of sedan chairs could not satisfy his ambition, and he started for Rome. The sight of the sea at Marseilles and his voyage thence to Civita Vecchia made a deep impression on him, and immediately after his arrival he entered the studio of a marine painter, Bernardino Fergioni. Slowly but surely Claude Joseph made his way and attracted notice. With a certain conventionality in design, proper to his day, he allied the results of constant and honest observation of natural effects of atmosphere, which he rendered with unusual pictorial art. Perhaps no painter of landscapes or sea-pieces has ever made the human figure so completely a part of the scene depicted or so important a factor in his design. "Others may know better," he said, with just pride, "how to paint the sky, the earth, the ocean; no one knows better than I how to paint a picture." For twenty years Vernet lived on in Rome, producing views of seaports, storms, calms, moonlights, &c., when he was recalled (1753) to Paris, and executed, by royal command, the remarkable series of the seaports of France (Louvre) by which he is best known. On his return he became a member of the academy, but he had previously contributed to the exhibitions of 1746 and following years, and he continued to exhibit, with rare exceptions, down to the date of his death, which took place in his lodgings in the Louvre on the 3rd of December 1789. Amongst the very numerous engravers of his works may be specially cited Le Bas, Cochin, Basan, Duret, Flipart and Le Veau in France, and in England Vivares.

II. Antoine Charles Horace Vernet (1758–1835), commonly called Carle, the youngest child of the above-named, was born at Bordeaux in 1758, where his father was painting the view from the château of La Trompette (Louvre). He showed, at the age of five, an extraordinary passion for drawing horses, but went through the regular academical course as a pupil of Lépicié. Strangely enough, on arriving in Italy after carrying off the *grand prix* (1782), he lost all ambition and interest in his profession, so that his father had to recall him to France to prevent his entering a monastery. In Paris Carle Vernet became himself again, and distinguished himself at the exhibition of 1791 by his "Triumph of Paulus Aemilius," a work in which he broke with reigning traditions in classical subjects and drew the horse with the forms he had learnt from nature in stables and riding-schools. But the Revolution drew on, and Carle Vernet's career for awhile seemed to end in the anguish of his sister's death on the scaffold. When he again began to produce, it was as the man of another era: his drawings of the Italian campaign brought him fresh laurels; his vast canvas, the "Battle of Marengo," obtained great success; and for his "Morning of Austerlitz" Napoleon bestowed on him the Legion of Honour. His hunting-pieces, races, landscapes, and work as a lithographer (chiefly under the Restoration) had also a great vogue. From Louis XVIII. he received the order of St Michael. In 1827 he accompanied his son Horace (see below) to Rome, and died in Paris on his return, on the 17th of November 1835.

III. Émile Jean Horace Vernet (1789–1863), commonly called Horace, born in Paris on the 30th of June 1789, was one of the most characteristic, if not one of the ablest, of the military painters of France. He was just twenty when he exhibited the "Taking of an Entrenched Camp"—a work which showed no depth of observation, but was distinguished by a good deal of character. His picture of his own studio (the rendezvous of the Liberals under the Restoration), in which he represented himself painting tranquilly, whilst boxing, fencing, drum- and horn-playing, &c., were going on, in the midst of a medley of visitors, horses, dogs and models, is one of his best works, and, together with his "Defence of the Barrier at Clichy" (Louvre), won for him an immense popularity. Enjoying equal favour with the court and with the opposition, he was most improperly appointed director of the school of France at Rome, from 1828 to 1835, and thither he carried the atmosphere of racket in which he habitually lived. After his return the whole of the Constantine room at Versailles was decorated by him in the short space of three years. This vast work shows Vernet at his best and at his worst: as a picture it begins and ends nowhere and the composition is all to pieces; but it has good qualities of faithful and exact representation. He died at Paris on the 17th of January 1863. The twenty works which were exhibited after his death confirmed his reputation for extraordinary facility; he had tried every sort of subject, showing affinity for all that was anecdotic rather than dramatic, failing most wherever most was demanded of him, and never reaching either beauty of colour or dignity of line. Vernet was, in short, a brilliant off-hand sketcher of all he saw, as he said himself, "from his window," and even in this work there was a good deal of affectation of the impromptu.

See Lagrange, *Joseph Vernet et la peinture au XVIII^e siècle* (1861); C. Blanc, *Les Vernet* (1845); A. Dayot, *Les Vernet* (1898).

VERNEUIL, PHILIPPE ÉDOUARD POULLETIER DE (1805–1873), French palaeontologist, was born in Paris on the 13th of February 1805. He was educated for the law, but being of independent means he was free to follow his own inclinations, and having attended lectures on geology by Élie de Beaumont he was so attracted to the subject that he devoted himself assiduously to the study of science. He spent several years in travel through various parts of Europe, specially examining the geology of the Crimea, on which he published an essay (*Mem. Sôc. Géol. France*, 1837). He next investigated the Devonian rocks and fossils of the Bas-Boulonnais; and in 1839 accompanied Sedgwick and Murchison in a study of the older Palaeozoic rocks of the Rhenish provinces and Belgium, the palaeontological results being communicated to the Geological Society of London in conjunction with D'Archiac. When Murchison commenced his geological examination of the Russian empire, he requested de Verneuil to accompany him, and the researches of the latter were incorporated in the second volume of *The Geology of Russia in Europe and the Ural Mountains* (1845). Subsequently de Verneuil paid a visit to the United States to study the history of the palaeozoic rocks in that country, and the results were published in 1847 (*Bull. Soc. Géol. France*). In later years he made numerous expeditions into Spain, and his observations were embodied in *Carte géologique de l'Espagne et du Portugal* (1864), prepared in association with E. Collomb. In 1853 the Wollaston medal of the Geological Society of London was awarded to him, and in 1860 he was elected a foreign member of the Royal Society. He died in Paris on the 29th of May 1873.

VERNEUIL, a town of north-western France, in the department of Eure, 34 m. S.S.W. of Evreux by rail. Pop. (1906) 3529. Verneuil, situated on the left bank of the Avre, has a number of old houses and churches. Of the latter the most important is the church of La Madeleine (11th to 17th century), the façade of which is flanked by an imposing square tower of the first half of the 16th century, similar in origin and appearance to the Tour de Beurre of Rouen cathedral. The church contains old stained glass, an ironwork pulpit and other works of art. The church of Notre Dame (12th and 16th centuries) possesses stone carvings of the Romanesque period and good stained glass. The Tour Grise is a fine cylindrical keep built in 1120 by Henry I., who fortified Verneuil as a stronghold for the Norman frontier. The town rose to considerable importance, and is said to have numbered as many as 25,000 inhabitants.

In 1424 the French were severely defeated by John, duke of Bedford, under the walls of Verneuil, which was then surrendered to the English; this victory confirmed the supremacy of the English over the country north of the Loire. The town was recaptured in 1449. It carries on ironfounding, dyeing and the manufacture of machinery.

VERNEY, the name of an English family which settled first of all at Fleetmarston in Buckinghamshire, then at Penley in Hertfordshire, and finally at Middle Claydon in Buckinghamshire. Its pedigree goes back to Ralph de Verney (fl. 1216–1223), but the fortunes of the family were made by Sir Ralph Verney (d. 1478), who was lord mayor of London in 1465 and M.P. for the city in 1472. His eldest son, Sir John Verney, married Margaret, heiress of Sir Robert Whittingham of Penley, and the fourth Sir Ralph Verney married in 1525 Elizabeth, one of the six co-heiresses of John, Lord Braye. Sir Edmund Verney of Penley (d. 1600) left two sons, half-brothers, Sir Francis Verney (1584–1615), who became a soldier of fortune and a buccaneer, and died at Messina in hospital in extreme poverty, and Sir Edmund Verney (1590–1642) of Middle Claydon, Bucks. Sir Edmund accompanied Prince Charles and Buckingham on the abortive mission to Madrid in 1623, and was knight-marshal to King Charles I. When the Civil War broke out the royal standard was entrusted to him at Nottingham, and while defending it he was slain at Edgehill in 1642. His eldest son, Sir Ralph Verney (1613–1696), 1st baronet, sat for Aylesbury in both the Short and the Long parliaments. He took the side of the parliament at the outset of the Civil War, but went abroad in 1643 rather than sign the Covenant, and his estates were sequestrated in 1646. He returned to England in 1653, and, though he refused to act against Cromwell, was subsequently reconciled to the Restoration government. His brother, Sir Edmund (1616–1649), had taken the king's side, and was one of those murdered in cold blood by Cromwell's soldiers at the sack of Drogheda. Sir Ralph Verney's estates and honours descended to his son, Sir John (*c.* 1640–1717), who was created Viscount Fermanagh in the Irish peerage in 1703 and was father of Ralph Verney, created Earl Verney in 1743. Earl Verney's sister, Margaret Verney, by her marriage with Sir Thomas Cave, linked the Verney family a second time with the barony of Braye, and the present Lord Braye's surname is Verney-Cave. Earl Verney's eldest son, John, predeceased him in 1737, leaving a posthumous daughter, Mary (1737–1810), who was created Baroness Fermanagh in 1792. His second son, Ralph, 2nd Earl Verney (*c.* 1712–1791), was a friend of Edmund Burke, who entered parliament as Verney's nominee for Wendover. Earl Verney was an ardent supporter of the Whig interest, but received no reward from the party leaders. He rebuilt Claydon House with great splendour from the plans of John Adam, but, with his financial ventures, this brought him to bankruptcy. He died childless in March 1791 and his titles became extinct.

The present Verney family, of Claydon Hall, Buckinghamshire, is descended in the male line from Felix Calvert (1596–1674) of Little Hadham, Hertfordshire. The Right Hon. Sir Harry Verney, 2nd baronet (1801–1894), was the son of General Sir Harry Calvert, G.C.B., created a baronet in 1818. He assumed the name of Verney in compliance with the will of Mary Verney, Baroness Fermanagh, mentioned above. This lady died unmarried, leaving the paternal estates and the Verney portraits to her half-sister, Catherine Calvert (Mrs Wright), known thenceforward as Mrs Verney, on whose death in 1827 they came into the possession of her cousin, Sir Harry Calvert (Verney). Sir Harry Verney entered the House of Commons for Buckingham in 1832, and remained a member of the House with two short intervals for fifty-two years. He married in 1835 Eliza, daughter of Admiral Sir George Johnstone Hope, K.C.B., M.P., and secondly Frances Parthenope Nightingale, sister of Florence Nightingale.

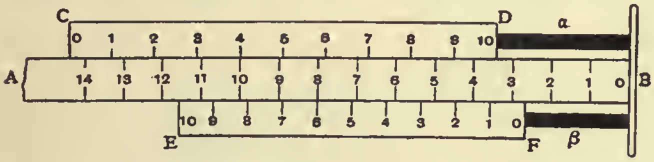
Frances, Lady Verney, collected from the mass of papers preserved at Claydon House the *Memoirs of the Verney Family during the Seventeenth Century*, which contain a charming picture of the life and manners of the country gentlemen of that day. A second edition, abridged and corrected by Margaret M. Verney, appeared in 2 vols. in 1904. See also the *Verney Papers* edited for the Camden Society in 1853–1854.

The Verneys who hold the barony of Willoughby de Broke descend from the Rev. Robert Barnard, prebendary of Winchester, who married in 1793 the Hon. Louisa Verney Peyto, daughter of John Peyto, 14th Baron Willoughby de Broke, and co-heiress of her brother Henry, 16th baron. The Peytos inherited the Verney estates in Warwickshire through Margaret Greville (d. 1631), sister and heiress of Fulke Greville, Lord Brooke (*q.v.*), who married Sir Richard Verney of Compton Murdac, Warwickshire. Robert John Barnard, 18th Baron Willoughby de Broke, who took in 1853 the surname of Verney in lieu of Barnard, was the grandfather of the 19th Lord Willoughby de Broke (Richard Greville Verney), who sat in the House of Commons from 1895 to 1900 for S.E. Warwickshire and succeeded to the title in 1902.

VERNIER, PIERRE (*c.* 1580–1637), inventor of the instrument which bears his name, was born at Ornans (near Besançon) in Burgundy about 1580. He was for a considerable time commandant of the castle in his native town. In 1631 he published at Brussels a treatise entitled *Construction, usage et propriétés du quadrant nouveau de mathématiques*, in which the instrument associated with his name is described. He died at Ornans in 1637.

The instrument invented by Vernier is frequently called a nonius, particularly in Germany, after Pedro Nuñez (1492–1577), professor of mathematics at the university of Coimbra; but this is incorrect, as the contrivance described by the latter in his work *De crepusculis* (1542) is a different one, although the principle is practically the same. Nuñez drew on the plane of a quadrant 44 concentric arcs divided respectively into 89, 88, ... 46 equal parts; and if the alidade did not coincide with one of the divisions on the principal arc, which was divided into 90 parts, the number of degrees in a quadrant, it would fall more or less accurately on a division line of one of the auxiliary arcs, from which the value of the measured angle could be made out. This instrument was, however, very difficult to make, and was but little used. Vernier proposed to attach to a quadrant divided into half-degrees a movable sector of a length equal to 31 half-degrees, but divided into 30 equal parts, whereby single minutes could be read off by seeing which division line of the "sector" coincided with a division line of the quadrant. The idea had been mentioned by Christopher Clavius (1537–1612) in his *Opera mathematica*, 1612 (ii. 5 and iii. 10), but he did not propose to attach permanently an arc divided in this way to the alidade; this happy application of the principle at all events belongs to Vernier.

The principle of the vernier is readily understood from the following account: Let AB (see fig.) be the normal scale, *i.e.* a scale graduated according to a standard of length, CD, a scale (placed in contact with AB for convenience) graduated so that 10 divisions equal 11 divisions of the scale AB, and EF a scale placed similarly and graduated so that 10 divisions equal 9 divisions of the scale AB. Consider the combination AB and CD. Obviously each division



of CD is $\frac{1}{10}$th greater than the normal scale division. Let a represent a length to be measured, placed so that one end is at the zero of the normal scale, and the other end in contact with the end of the vernier CD marked 10. It is noted that graduation 4 of the vernier coincides with a division of the standard, and the determination of the excess of a over 3 scale divisions reduces to the difference of 7 divisions of the normal scale and 6 divisions of the vernier. This is ·4, since each vernier division equals 1·1 scale division. Hence the scale reading of the vernier which coincides with a graduation of the normal scale gives the decimal to be added to the normal scale reading. Now consider the scales AB and EF, and let β be the length to be measured; the scale EF being placed so that the zero end is in contact with an end of β. Obviously each division of EF is $\frac{1}{10}$th less than that of the normal scale. It is seen that division 6 of the vernier coincides with a normal scale division, and obviously the excess of β over two normal scale divisions equals the difference between 6 normal scale divisions and 6 vernier divisions, *i.e.* 0·6. Thus again in this case the vernier reading which coincides with a scale reading gives the decimal to be added to the normal scale. The second type of vernier is that more commonly adopted, and its application to special appliances is quite simple. For example, the normal scale to an English barometer is graduated in $\frac{1}{20}$ths of an inch. The vernier is such that 24 divisions of the normal scale equal 25 of the vernier; each of the latter therefore is ·002 or $\frac{1}{500}$th inch less than the normal division. In the scientific barometer, the normal scale is graduated in millimetres, and the vernier so that 20 scale divisions equal 19 mm. This combination reads to 0·05 mm.

VERNIS MARTIN, a generic name, derived from a distinguished family of French artist-artificers of the 18th century, given to a brilliant translucent lacquer extensively used in the decoration of furniture, carriages, sedan chairs and a multitude of small articles such as snuff-boxes and fans. There were four brothers of the Martin family: Guillaume (d. 1749), Simon Étienne, Julien and Robert (1706–1765), the two first-named being the elder. They were the children of Étienne Martin, a tailor, and began life as coach-painters. They neither invented, nor claimed to have invented, the varnish which bears their name, but they enormously improved, and eventually brought to perfection, compositions and methods of applying them which were already more or less familiar. Oriental lacquer speedily acquired high favour in France, and many attempts were made to imitate it. Some of these attempts were passably successful, and we can hardly doubt that many of the examples in the possession of Louis XIV. at his death were of European manufacture. Chinese lacquer was, however, imported in large quantities, and sometimes panels were made in China from designs prepared in Paris, just as English coats of arms were placed upon Chinese porcelain in its place of origin. Biographical details of the career of the brothers Martin are scanty, but we know that the eldest was already in business in 1724. Their method and work must have come rapidly into vogue, for in 1730 Guillaume and Simon Étienne Martin were granted by letters patent a twenty years' monopoly, subsequently renewed, of making " toutes sortes d'ouvrages en relief de la Chine et du Japon." At the height of their fame the brothers directed at least three factories in Paris, and in 1748 they were all classed together as a " Manufacture nationale." One of them was still in existence in 1785. The literature of their day had much to say of the frères Martin. In Voltaire's comedy of *Nadine*, produced in 1749, mention is made of a *berline* " bonne et brillante, tous les panneaux par Martin sont vernis "; also in his *Premier discours sur l'inégalité des conditions* he speaks of " des lambris dorés et vernis par Martin." The marquis de Mirabeau in *L'Ami des hommes* refers to the enamelled snuff-boxes and varnished carriages which came from the Martins' factory. It is the fate of all the great artists of the past to have had their names attached, by popular rumour or interested artifice, to a multitude of works which they never saw, and the Martins have suffered considerably in this respect. That the quality of their production varied between very wide limits is established by existing and undoubted examples; but it is extremely improbable that even their three factories could have turned out the infinite quantity of examples that has been attributed to them. Yet their production was large and exceedingly miscellaneous, for such was the rage for their lacquer that it was applied to every possible object. Nor need we be surprised at a rage which was by no means confined to France. At its best Vernis Martin has a splendour of sheen, a perfection of polish, a beauty of translucence which compel the admiration due to a consummate specimen of handiwork. Every variety of the lacquer of the Far East was imitated and often improved upon by the Martins—the black with raised gold ornaments, the red, and finally in the wonderful green ground, powdered with gold, they reached the high-water mark of their delightful art. This delicate work, *poudré* and wavy-lined with gold or *semé* with flowers overlaid with transparent enamel, is seen at its best on small boxes, fans, needle-cases and such-like. Of the larger specimens from the Martins' factories a vast quantity has disappeared, or been cut up into decorative panels. It would appear that none of the work they placed in the famous hotels of old Paris is now *in situ*, and it is to museums that we must go for really fine examples—to the Musée de Cluny for an exquisite children's sedan chair and the coach used by the French ambassador to Venice under Louis XV.; to the Wallace collection for the tables with richly chased mounts that have been attributed to Dubois; to Fontainebleau for a famous commode. Even the decorations of the apartments of the dauphin at Versailles, executed, or at least begun, in 1749, have vanished; so have those at Bellevue. It has been generally accepted that of the four brothers Robert Martin accomplished the most original and the most completely artistic work. He left a son, Jean Alexandre, who described himself in 1767 as " Vernisseur du Roi de Prusse." He was employed at Sans Souci, but failed to continue the great traditions of his father and his uncles. The Revolution finally extinguished a taste which had lasted for a large part of the 18th century. Since then the production of lacquer has, on the whole, been an industry rather than an art. (J. P.-B.)

VERNON, EDWARD (1684–1757), English admiral, was born in Westminster on the 12th of November 1684. He was the second son of James Vernon, secretary of state from 1697–1700, a scion of an ancient Staffordshire family who is best remembered by three volumes of his letters to the duke of Shrewsbury, which were published in 1841; and his mother was Mary, daughter of Sir John Buck of Lincolnshire. Edward Vernon was sent to Westminster school at the age of seven, and remained there till he was sixteen. Outside its walls he studied, with a view to his future profession, such branches of knowledge as geometry, geography and the construction of military weapons. He entered the navy in 1701, and from that time until 1707 took part in many expeditions in the Mediterranean and the West Indies. He served with Sir George Rooke at the taking of Gibraltar in July 1704; and on his return to England Queen Anne acknowledged his gallantry with the present of two hundred guineas. He next served in the West Indies with Commodore Sir Charles Wager, a brave seaman, who afterwards rose to the highest position at the admiralty in the Whig ministry of Walpole, and was pitted against Vernon both in the House of Commons and at the polling-booth. In 1715, and again in 1726, Vernon assisted in the naval operations in the Baltic, supporting Sir John Norris in the first enterprise, and on the latter serving under his old chief, Sir Charles Wager. During the long supremacy of Walpole little opportunity arose for distinction in warfare, and Vernon's energies found relief in politics. At the general election of 1722 he was returned for both Dunwich in Suffolk and Penryn in Cornwall, but chose the latter constituency. In the succeeding parliament of 1727 he was again chosen member for Penryn; but he failed to retain his seat after the dissolution in 1734. At this period the English people regarded the Spaniards as their legitimate enemies, and the ill-feeling of the two countries was fanned both in poetry and in prose. The political antagonists of Walpole charged him with pusillanimity to Spain. With Pulteney and most of his associates this battle-ground was selected rather from expediency than from principle; but Vernon represented the natural instincts of the sea-captain, and with the sailor as with the soldier the motto was "No peace with Spain." In debate he spoke often, and frequently with effect, but his language always savoured of extravagance. He pledged himself in 1739 to capture Porto Bello with a squadron of but six ships, and the minister whom he had assailed with his invectives sent him, as vice-admiral of the blue and commander of the fleet in the West Indies, to the enterprise with the force which he had himself called sufficient. Vernon weighed anchor from Spithead on the 23rd of July 1739 and arrived off Porto Bello on 20th November. Next day the combat began with a bombardment of an outlying fort which protected the mouth of the harbour, and on the 22nd of November the castle and town surrendered with a loss on the English side of only seven men. The joy of the nation knew no bounds. Vernon's birthday was celebrated in 1740 in London with public illuminations, and 130 medals were struck in his honour. In February 1741 in a by-election at Portsmouth Vernon was again sent to parliament. At the general election in the following May he was returned for Ipswich, Rochester and Penryn, and all but succeeded in winning Westminster.[1] He elected to sit for Ipswich. A larger squadron was placed under Vernon's command at the close of 1740, and with this force he resolved upon attacking Cartagena. After a fierce struggle, the castle, which stood at the harbour's entrance, was gained; but in the attack upon the city the troops and sailors failed to act in concert, and, with the numbers of his forces thinned by combat and by disease, the British admiral retired to Jamaica. The incidents of this disastrous attempt are described in Smollett's *Roderick Random*, chap. xxxi., &c. A similar enterprise in July 1741 against Santiago de Cuba met with a similar reverse, and Vernon attributed the defeat to the divided command of the British forces. During his command he did a good deal for the health of his crews. He first introduced the custom of mixing the rum served to the sailors in the West Indies with water. The word "grog" is said to be derived from the nickname of "old Grog" given him by the sailors, because he wore a peculiar grogram boat-cloak. He landed at Bristol on the 6th of January 1743, and on the 24th of January received the freedom of the city of London. When the country dreaded the march of Prince Charles to London, the fleet in the Downs was placed under the command of Vernon; but his jealous disposition brooked no interference from the admiralty, and on the 1st of January 1746 he struck his flag and handed over the command to another. His next act was to describe his grievances in a couple of angry pamphlets, revealing the communications of his official chiefs, and for this indiscretion he was struck off the list of flag officers (April 11, 1746). He continued to represent the borough of Ipswich until his death, but with this proceeding his public services practically ceased. He died suddenly at Nacton in Suffolk, the 30th of October 1757, and was buried in the church of the village.

[1] Grego's *Parliamentary Elections* (London, 1886), pp. 95–106.

Vernon's gallantry was unquestioned; but his valour not infrequently degenerated into foolhardiness, and he dwelt more often than is usual with British seamen on the merits of his own exploits. His politics were those of the Tory party, and his differences with the Whigs and with his colleagues in the services led to his publishing several pamphlets on his political conduct. A *Memorial of Admiral Vernon from Contemporary Authorities* was printed by W. F. Vernon for private circulation in 1861.

VERNON, a town of north-western France, in the department of Eure, 19 m. E.N.E. of Evreux by road. Pop. (1906) 7274. Vernon stands on the left bank of the Seine opposite the forest of Vernon, a stone bridge uniting it to Vernonnet on the right bank, where there are important stone quarries. The forest of Bizy lies to the south of the town. Its church is an interesting building dating from the 12th to the 15th centuries, and there is a cylindrical keep built by Henry I. of England. The port on the Seine carries on trade in stone and coal, and the town has workshops for the manufacture of army engineering material and manufactures benzine, aniline dyes, wooden shoes, liqueurs, &c.

Vernon in 1196 was ceded by its count to Philip Augustus, Richard I. resigning his suzerainty. The first Estates of Normandy were held at Vernon in 1452.

VEROLI (anc. *Verulae*), a town and episcopal see of the province of Rome, Italy, 10 m. by road N.E. of Frosinone, 1870 ft. above sea-level. Pop. (1901) 2622 (town); 12,655 (commune). The town is situated on a hill in a strong position with a fine view, on the site of the ancient Hernican town of Verulae, 7 m. S.E. of Aletrium. It retains remains of its ancient polygonal enceinte, especially near the summit of the hill, later occupied by a medieval castle. It is hardly mentioned in history: we know that it became a municipium in 90 B.C. The cathedral treasury contains the breviary of S. Louis of Toulouse, and some interesting reliquaries, one in ivory with bas-reliefs, and two in the Gothic style, of silver gilt.

VÉRON, LOUIS DÉSIRÉ (1798–1867), French publicist, was born at Paris on the 5th of April 1798. In 1829 he founded the *Revue de Paris*, and from 1838 to 1852 was owner and director of the *Constitutionnel*, in which he published in Eugène Sue's *Wandering Jew*. It was also during Véron's direction and at his suggestion that Sainte-Beuve contributed the *Causeries du lundi*. From 1831–1835 he was director of the Paris Opera. In 1852 he was elected to the Corps Législatif as an official candidate. He was the author of various books, of which the best known is *Mémoires d'un bourgeois de Paris* (1853–1855). He died in Paris on the 27th of September 1867.

VÉRON, PIERRE (1831–1900), French publicist, was born in Paris on the 19th of April 1831, and in 1854 published his first book, a volume of verse. In 1858 he joined the staff of *Charivari*, and edited that paper from 1865–99. He was the author of a large number of novels dealing with Parisian life, and for many years his rooms in the Rue de Rivoli were the meeting-place of the most famous French literary, artistic and political celebrities. He died in Paris on the 2nd of November 1900.

VERONA, a city and episcopal see of Venetia, Italy, the capital of the province of Verona, situated 194 ft. above sea-level in a loop made by the winding of the Adige (anc. *Athesis*). Pop. (1906) 61,618 (town); 79,574 (commune). It is 93 m. E. of Milan and 71 m. W. of Venice by rail, and is also the point of departure of the main lines to Mantua and Modena and to the Brenner, while a branch line runs N.W. to Caprino, another S.E.

to Legnago, and steam tramways to Cologna Veneta, Coriano and S. Giacomo.

The basilica of S. Zeno (an early bishop of Verona who became its patron saint), which stands outside the ancient city, is one of the most interesting Romanesque churches in Italy. ***Churches.*** The church was remodelled in 1139, to which period much of the existing structure belongs, including the richly sculptured west front and the open *confessio* or crypt, which occupies the eastern half of the church, raising the choir high above the nave. The nave, dating from the 11th century, is supported by alternate columns and pillars, and contains frescoes of the 11th-14th centuries. The cloisters of S. Zeno, rebuilt in 1123, are an interesting example of brick and marble construction. Like many other churches in Verona, S. Zeno is mainly built of mixed brick and stone in alternate bands: four or five courses of fine red brick lie between bands of hard cream-coloured limestone or marble, forming broad stripes of red and white all over the wall. A similarly variegated effect in red and white is produced by building the arches of windows and doors with alternating voussoirs in brick and marble. The neighbourhood of Verona is especially rich in fine limestones and marbles of many different kinds, especially a close-grained cream-coloured marble and a rich mottled red marble, which are largely used, not only in Verona, but also in Venice and other cities of the province. The same quarry produces both kinds, and indeed the same block is sometimes half red and half white. On the north side of the church is a lofty tower, called the tower of Peppin; while the slender brick campanile on the south dates from 1045 to 1178.

The cathedral, consecrated in 1187 by Pope Urban III., stands at the northern extremity of the ancient city, by the bank of the Adige; it is inferior in size and importance to S. Zeno, but has a fine 12th-century west front of equal interest, richly decorated with naïve Romanesque sculpture (1135). The rest of the exterior is built in bands of red and white, with slightly projecting pilasters along the walls; it has a noble cloister, with two storeys of arcading. The campanile by Sanmichele is unfinished. Its baptistery, rebuilt early in the 12th century, is a quite separate building, with nave and apse, forming a church dedicated to S. Giovanni in Fonte. Pope Lucius III., who held a council at Verona in 1184, is buried in the cathedral, under the pavement before the high altar. The Dominican church of S. Anastasia is a mine of wealth in early examples of painting and sculpture, and one of the finest buildings in Italy of semi-Gothic style. It consists of a nave in six bays, aisles, transepts, each with two eastern chapels, and an apse, all vaulted with simple quadripartite brick groining. It was begun in 1261, but not completed till 1422, and is specially remarkable for its very beautiful and complete scheme of coloured decoration, much of which is contemporary with the building. The vaults are gracefully painted with floreated bands along the ribs and central patterns in each "cell," in rich soft colours on a white plastered ground. The eastern portion of the vaulting, including the choir and one bay of the nave, has the older and simpler decorations; the rest of the nave has more elaborate painted ornament—foliage mixed with figures of Dominican saints, executed in the 15th century. There are many fine frescoes in the interior ranging from *c.* 1300 (knights kneeling before the Virgin) to the 15th century, including Pisanello's beautiful painting of St George (mentioned below). This church also contains a large number of fine sculptured tombs of the 14th and 15th centuries, with noble effigies and reliefs of saints and sacred subjects. It is mainly built of red brick, with fine nave columns of red and white marble and an elaborate marble pavement inlaid in many different patterns. Its general proportions are specially noble, and the exterior view is good. The church of S. Fermo Maggiore comes next in interest. With the exception of the crypt, which is older, the existing edifice was rebuilt in 1313. The façade is of brick and marble used alternately. The plan is unusual, consisting of a large nave without aisles, the span being between 45 and 50 ft.; it also has two shallow transepts and an apsidal east end. The roof, which is especially magnificent, is the finest example of a class which as a rule is only found in Venetia or in churches built by Venetian architects in Istria and other subject provinces: the framing is concealed by coving or barrel-vaulting in wood, the surface of which is divided into small square panels, all painted and gilt, giving a very rich effect. In this case the 14th and 15th century painted decorations are well preserved. Delicate patterns cover all the framework of the panelling and fill the panels themselves; at two stages, where there is a check in the line of the coving, rows of half-figures of saints are minutely painted on blue or gold grounds, forming a scheme of indescribably splendid decoration. A simpler roof of the same class exists at S. Zeno; it is trefoil-shaped in section, with a tie-beam joining the cusps. The church of S. Maria in Organo, dating from 1481, with a façade of 1592 from Sanmichele's designs, contains paintings by various Veronese masters, and some fine choir-stalls of 1499 by Fra Gioconda. Though not built till after his death, the church of S. Giorgio in Braida, on the other side of the river, was also designed by Sanmichele, and possesses many good pictures of the Veronese school. The Romanesque church of S. Lorenzo, restored in 1896–1898, contains old frescoes. S. Stefano is another Romanesque church, probably of the 11th century. There are several other fine churches in Verona, some of early date. One of the 14th century is dedicated to Thomas à Becket of Canterbury.

The strongly fortified castle (Castel Vecchio) built by the Della Scala lords in the 14th century stands on the line of the wall of Theodoric, close by the river. A very picturesque battlemented bridge leads from it to the other shore, sloping down over three arches of different sizes, the largest next to the castle and the smallest at the other end. ***Bridges and fortifications.*** There are four other bridges across the Adige: one, the graceful Ponte di Pietra, rests upon ancient foundations, while the two arches nearest to the left bank are Roman; but it has been frequently restored. Remains of another ancient bridge were found in the river itself in 1891 behind S. Anastasia. The 16th-century lines of fortification enclose a very much larger area than the Roman city, forming a great loop to the west, and also including a considerable space on the left bank of the river. In the latter part of the city, on a steep elevation, stands the castle of St Peter, originally founded by Theodoric, on the site, perhaps, of the earliest citadel, mostly rebuilt by Gian Galeazzo Visconti in 1393, and dismantled by the French in 1801. This and the other fortifications of Verona were rebuilt or repaired by the Austrians, but are no longer kept up as military defences. Verona, which is the chief military centre of the Italian province of Venetia, is now being surrounded with a circle of forts far outside the obsolete city walls.

The early palaces of Verona, before its conquest by Venice, were of noble and simple design, mostly built of fine red brick, with an inner court, surrounded on the ground floor by open arches like a cloister, as, for example, the ***Palaces.*** Palazzo della Ragione, an assize court, begun in the 12th century. The arches, round or more often pointed in form, were decorated with moulded terra-cotta enrichments, and often with alternating voussoirs of marble. The Scaligeri Palace is a fine example, dating from the 14th century, with, in the cortile, an external staircase leading to an upper loggia, above the usual arcade on the ground floor. It has a lofty campanile, surmounted by a graceful octagonal upper storey. This palace is said to have been mainly built by Can Signorio (Della Scala) about 1370. After the conquest by Venice the domestic buildings of Verona assumed quite a different type. They became feeble copies of Venetian palaces, in which one form of window, with an ogee arch, framed by the dentil moulding, is almost always used. The monotony and lifelessness of this form of architecture are shown in the meaningless way in which details, suited only to the Venetian methods of veneering walls with thin marble slabs, are copied in the solid marbles of Verona. From the skill of Fra Giocondo, Verona was for many years one of the chief centres in which the most refined and graceful forms of the early Renaissance were developed. The town hall, with its light open loggia of semicircular arches on the ground floor, was designed by Fra Giocondo towards the end of the 15th century; its sculptured enrichments of pilasters and friezes are very graceful, though lacking the vigorous life of the earlier medieval sculptured ornamentation. Verona contains a number of handsome palaces designed by Sanmichele in the 16th century. The finest are those of the Bevilacqua,[1] Canossa and Pompeii families. The last of these is now the property of the city, and contains a gallery with some good pictures, especially of the Verona, Padua and Venice schools. As in Venice, many of the 16th-century palaces in Verona had stuccoed façades, richly decorated with large fresco paintings, often by very able painters. Verona, perhaps, had as many of these paintings as any town in Italy, but comparatively few are preserved and those only to a small extent. The domestic architecture of Verona cannot thus be now fairly estimated, and seems monotonous, heavy and uninteresting. The house of the painter Niccolo Giolfino still has its frescoes in a good state of preservation, and gives a vivid notion of what must once have been the effect of these gorgeous pictured palaces. The episcopal palace contains the ancient and valuable chapter library, of about 12,000 volumes and over 500 MSS., among them the palimpsest of the *Institutiones* of Gaius which Niebuhr discovered. The Piazza delle Erbe (fruit and vegetable market) and the Piazza dei Signori, adjoining one another in the oldest part of the city, are very picturesque and beautiful, being surrounded by many fine medieval buildings, several of them of a public character (Palazzo dei Giureconsulti, Palazzo della Ragione and the lofty Torre Civica, 273 ft. high), while in the north-east corner of the latter Piazza is the fine early Renaissance Palazzo del Consiglio (1476–1492), probably designed by Fra Giocondo. In the former Piazza a copy of the lion of Venice has been erected.

Squares.

Roman remains.

The Roman remains of Verona surpass those of any other city of northern Italy. The most conspicuous of them is the great amphitheatre, a building perhaps of the end of the 1st century A.D., which in general form closely resembled the Colosseum in Rome. Its axes measured 505 and 404 ft. Almost the whole of its external arcades, with three tiers of arches, have now disappeared; it was partly thrown down by an earthquake in 1184, and subsequently used to supply building materials. Many of its blocks are still visible in the walls of various medieval buildings. The interior, with seats for about 25,000 people, has been frequently restored, till nothing of the old seats exists. There are also remains of a well-preserved Roman theatre, close to the left bank of the river. A number of fine sculptures were found in the square in front of the cathedral in 1890, and architectural fragments belonging to some public building. In 1884–86 portions of a number of fine mosaic pavements were discovered extending over a very large area under the cloister and other parts of the cathedral, about 7 ft. below the present ground level. They had geometric patterns with birds, trees, &c., and bore inscriptions in mosaic with the names of the donors. Parts of them had been discovered previously. They seem to belong to two different buildings, both early churches of the 5th and 6th centuries A.D. (cf. *Notizie degli Scavi*, 1884, 401). For the two triumphal arches (Porta dei Bosari and Porta dei Leoni) see below. The Museo Lapidario contains a fine collection of Roman and Etruscan inscriptions and sculpture, mostly collected and published by Scipione Maffei in the 18th century.

Veronese Art.—In many respects the resemblance between Verona and Florence is very striking; in both cases we have a strongly fortified city built in a fertile valley, on the banks of a winding river, with suburbs on higher ground, rising close above the main city. In architectural magnificence and in wealth of sculpture and painting Verona almost rivalled the Tuscan city, and, like it, gave birth to a very large number of artists who distinguished themselves in all branches of the fine arts.

Painting.

Painting in Verona may be divided into four periods. (i.) The first period is characterized by wall paintings of purely native style, closely resembling the early Christian pictures in the catacombs of Rome. Examples dating from the 10th to the 11th century have been discovered hidden by whitewash on the oldest parts of the nave walls of the church of S. Zeno. They are a very interesting survival of the almost classical Roman style of painting, and appear to be quite free from the generally prevalent Byzantine influence. (ii.) The Byzantine period seems to have lasted during the 12th and 13th centuries. (iii.) The Giottesque period begins contemporaneously with Altichiero da Zevio and Giacomo degli Avanzi, whose chief works were executed during the second half of the 14th century. These two painters were among the ablest of Giotto's followers, and adorned Verona and Padua with a number of very beautiful frescoes, rich in composition, delicate in colour, and remarkable for their highly finished modelling and detail. (iv.) To the fourth period belong several important painters. Pisanello or Vittore Pisano, a charming painter and the greatest medallist of Italy, was probably a pupil of Altichiero.[2] Most of his frescoes in Verona have perished; but one of great beauty still exists in a very perfect state in the church of S. Anastasia, high up over the arched opening into one of the eastern chapels of the south transept. The scene represents St George and the Princess after the conquest of the Dragon, with accessory figures, the sea, a mountainous landscape and an elaborately painted city in the background. The only other existing fresco by Pisanello is an Annunciation in S. Fermo Maggiore. For Pisanello's pupils and other painters of subsequent date, see PAINTING. These include Liberale da Verona, Domenico and Francesco Morone, Girolamo dai Libri (1474–1556), &c. Domenico del Riccio, usually nicknamed Brusasorci (1494–1567), was a prolific painter whose works are very numerous in Verona. Paolo Cagliari or Paul Veronese, and the Bonifagios, though natives of Verona, belong rather to the Venetian school.

Sculpture.

Verona is specially rich in early examples of decorative sculpture. (i.) The first period is that of northern or Lombardic influence, exemplified in the very interesting series of reliefs which cover the western façades of the church of S. Zeno and the cathedral, dating from the 12th century. These reliefs represent both sacred subjects and scenes of war and hunting, mixed with grotesque monsters, such as specially delighted the rude, vigorous nature of the Lombards; they are all richly decorative in effect, though strange and unskilful in detail. Part of the western bronze doors of S. Zeno are especially interesting as being among the earliest important examples in Italy of cast bronze reliefs. They are frequently stated to be of beaten bronze, but they are really castings, apparently by the *cire perdue* process. They represent scenes from the life of S. Zeno, are rudely modelled, and yet very dramatic and sculpturesque in style. Parts of these doors are covered with bronze reliefs of scenes from the Bible, which are of still earlier date, and were probably brought to Verona from the Rhine provinces. Many of the 12th century reliefs and sculptured capitals in S. Zeno are signed by the sculptor but these merely constitute lists of names about whom nothing is known. (ii.) In the 13th century the sculpture seems to have lost the Lombard vigour, without acquiring any qualities of superior grace or refinement. The font in the baptistery near the cathedral is an early example of this. Each side of the octagon is covered with a large relief of a Biblical subject, very dull in style and coarse in execution. The font itself is interesting for its early form, one common in the chief baptisteries of northern Italy: like an island in the centre of the great octagonal tank is a lobed marble receptacle, in which the officiating priest stood while he immersed the catechumens. A movable wooden bridge must have been used to enable the priest to cross the water in the surrounding tank. (iii.) The next period is that of Florentine influence. This is exemplified in the magnificently sculptured tombs of the Della Scala lords, designed with steadily growing splendour, from the simple sarcophagus of Martino I. down to the elaborate erection over the tomb of the fratricide Can Signorio, adorned with statuettes of the virtues, to the possession of which he could lay so little claim.[3] The recumbent effigies and decorative details of these tombs are very beautiful, but the smaller figures of angels, saints and virtues are rather clumsy in proportion. The latest tomb, that of Can Signorio, erected during his lifetime (*c.* 1370), is signed "Boninus de Campigliono Mediolanensis Dioecesis." This sculptor, though of Milanese origin, belongs really to the school of the Florentine Andrea Pisano. One characteristic of the 14th and 15th centuries in Verona was the custom, also followed in other Lombardic cities, of setting large equestrian statues over the tombs of powerful military leaders, in some cases above the recumbent effigy of the dead man, as if to represent him in full vigour of life as well as in death. That which crowns the canopy over the tomb of Can Grande is a very noble, though somewhat quaint, work. (iv.) In the 15th century the influence of Venice became paramount, though this was really only a further development of the Florentine manner, Venice itself having been directly influenced in the 14th century by many able sculptors from Florence.

Architecture.

The architecture of Verona, like its sculpture, passed through Lombard, Florentine and Venetian stages. (i.) The church of S. Zeno and the cathedral, both of which were mainly rebuilt in the 12th century, are noble examples of the Lombardic style, with few single-light windows, and with the walls decorated externally by series of pilasters, and by alternating bands of red and white, in stone or brick. The arches of this period are

[1] The valuable collection of works of art once preserved in the Bevilacqua Palace has long been dispersed.

[2] There is every reason to doubt Vasari's statement that Pisanello was a pupil of Andrea del Castagno.

[3] See an eloquent description by Ruskin, *Stones of Venice*, iii. pp. 70 seq.

semicircular and rest on round columns and capitals, richly carved with grotesque figures and foliage. Most of the external ornamentation is usually concentrated on the western front, which often has a lofty arched porch on marble columns, resting on griffins or lions devouring their prey. (ii.) The Florentine period (*c.* 1250 to 1400) is represented by the church of S. Anastasia, and by many more or less mutilated palaces, with fine courts surrounded by arcades in one or more storeys. The arches are mostly pointed, and in other respects the influence of northern Gothic was more direct in Verona than in Florence. Solidity of mass and simplicity of detail are among the characteristics of this period. (iii.) The Venetian period (*c.* 1400–1480) was one of little originality or vigour, the buildings of this date being largely rather dull copies of those at Venice. (iv.) The early Renaissance developed into very exceptional beauty in Verona, mainly through the genius of Fra Giocondo (1435–1514), a native of Verona, who was at first a friar in the monastery of S. Maria in Organo. He rose to great celebrity as an architect, and designed many graceful and richly sculptured buildings in Venice, Rome and even in France; he used classical forms with great taste and skill, and with much of the freedom of the older medieval architects, and was specially remarkable for his rich and delicate sculptured decorations. Another of the leading architects of the next stage of the Renaissance was the Veronese Michele Sanmichele (1484–1559), a great military engineer, and designer of an immense number of magnificent palaces in Verona and other cities of Venetia. His buildings are stately and graceful in proportion, but show a tendency towards dull scholastic classicism. The façades of his palaces were in the lower storey only decorated by rustication, of which he made great use, while the upper part was intended to be decorated with frescoes, which (as we have said) have in most cases perished. To him are also due the various gates and the most important bastions in the walls of Verona. In consequence of the disastrous flood of 1882, important embankment works were executed along the Adige at a cost of £300,000. These works preclude all danger of future inundation. In addition to the Adige embankment, other hydraulic works have been either completed or undertaken. An irrigation canal, deriving water from the Sega, furnishes 11½ cubic metres per second to the fields of the upper Veronese district. The Camuzzoni industrial canal, which runs from the Chievo di S. Massimo to the suburb of Tombetta, furnishes 26 cubic metres of water per second, and generates 4000 horse-power. The cutting of this canal led to the construction of an aqueduct for drinking water, which, besides supplying the city, furnishes an ice factory with enough water to make 200 quintals of ice per day. The motive-power generated by the Camuzzoni canal is utilized by a large nail factory, flour mills, paper mills, cotton mills and works for the distribution of electric energy.

The Adige embankment gave an impetus to building enterprise, the banks of the river being now flanked by villas and large dwelling-houses.

History.—The ancient Verona was a town of the Cenomani, a Gaulish tribe, whose chief town was Brixia. It became a Latin colony in 89 B.C. and, acquiring citizenship with the rest of Gallis Transpadana in 49 B.C., became a *municipium.* Tacitus wrongly speaks of it as a colony; but it appears to have received a new colony under Gallienus. In the time of Augustus it was inferior to Patavium in importance, but on a par with Mediolanum, and superior to Brixia and other towns of the district. Inscriptions testify to its importance—among others one which indicates that it was the headquarters of the collectors of the 5% inheritance tax under the Empire in Italy beyond the Po. Its territory stretched as far as Hostilia on the Padus (Po), 30 m. to the south, and was extensive on other sides also, though its exact limits are uncertain. It was an important point in the road system of the district, lying on that between Mediolanum and Aquileia, while here diverged to the north the roads up the Athesis valley and over the Brenner into Raetia, and to the south roads ran to Betriacum, Mantua and Hostilia. It was the birthplace of the poet Catullus. In A.D. 69 it became the headquarters of the legions which were siding with Vespasian. Its fertile surroundings, its central position at the junction of several great roads, and the natural strength of its position, defended by a river along two-thirds of its circumference, all combined to make Verona one of the richest and most important cities in northern Italy, although its extent within the walls was not large. The existing remains of walls and gates date from the period between the 3rd of April and the 4th of December of the year 265. A very handsome triumphal arch, now called the Porta de' Borsari, was restored in this year by Gallienus (as the inscription upon it, which has taken the place of an older one, cancelled to make room for it, records), and became one of the city gates. It is a double arch, and above it are two orders of smaller arcades. The same was the case with the Porta dei Leoni, another rather similar triumphal arch on the east of the city, and with a third arch, the Arco dei Gavi, demolished in 1805. This last seems to have belonged to the 1st century A.D.; remains of it are preserved in the amphitheatre. It took its name from the family in whose honour it was erected; the architect was one L. Vitruvius Cerdo, possibly a pupil and freedman of the famous writer on architecture. The Porta dei Leoni, on the other hand, bears the name of Tiberius Flavius Noricus, a *quattuorvir iure dicundo, i.e.* one of the four chief magistrates of the city (probably 2nd century A.D.). The original line of walls did not include the amphitheatre, but passed N.E. of it; it was, however, afterwards included in the *enceinte* as a kind of massive corner tower.[1] The emperor Constantine, while advancing towards Rome from Gaul, besieged and took Verona (312); it was here, too, that Odoacer was defeated (499) by Theodoric the Goth, Dietrich von Bern—*i.e.* Verona—of German legends, who built a castle at Verona and frequently resided there. He enlarged the fortified area by constructing a wall and ditch (now called Adigetto) straight across the loop, to the S.W. of the amphitheatre, and also built thermae and restored the acqueducts, which had long been out of use.

In the middle ages Verona gradually grew in size and importance. Alboin, the Lombard king, captured it in 568, and it was one of the chief residences of the Lombard, and later of the Frankish, monarchs; and though, like other cities of northern Italy, it suffered much during the Guelph and Ghibelline struggles, it rose to a foremost position both from the political and the artistic point of view under its various rulers of the Scaliger or Della Scala family. The first prominent member of this family and founder of his dynasty was Mastino I. della Scala, who ruled over the city from 1260 till his death in 1277. Verona had previously fallen under the power of a less able despot, Ezzelino da Romano, who died in 1259. Alberto della Scala (died in 1301) was succeeded by his eldest son Bartolomeo, who was confirmed as ruler of Verona by the popular vote, and died in 1304. It was in his time that Romeo and Juliet are said to have lived. Alboino, the second son, succeeded his brother, and died in 1311, when the youngest son of Alberto, Can Grande, who since 1308 had been joint-lord of Verona with his brother, succeeded to the undivided power. Can Grande (Francesco della Scala, d. 1329) was the best and most illustrious of his line, and is specially famous as the hospitable patron of Dante (*q.v.*). Other princes of this dynasty, which lasted for rather more than a century, were Giovanni (d. 1350), Mastino II. (d. 1351), Can Grande II. (d. 1359) and Can Signorio (d. 1375). In 1389 Gian Galeazzo Visconti, duke of Milan, became by conquest lord of Verona. Soon after his death the city fell by treacherous means into the hands of Francesco II. di Carrara, lord of Padua. In 1404–1405 Verona, together with Padua, was finally conquered by Venice, and remained subject to the Venetians till the overthrow of the republic by Napoleon in 1797, who in the same year, after the treaty of Campo Formio, ceded it to the Austrians with the rest of Venetia. They fortified it strongly in 1814, and with Peschiera, Mantua and Legnago it formed part of the famous quadrilateral which until 1866 was the chief support of their rule in Italy.

See the various works by Scipione Maffei (*Verona Illustrata*, 1728; *Museum Veronense*, 1749); and Th. Mommsen in *Corp. Inscr. Latin* (Berlin, 1883), v. p. 327 (with bibliography); A. Wiel, *The Story of Verona* (London, 1902); *Notizie degli scavi*, passim; E. Giani, *L' Antico teatro di Verona* (Verona, 1908).

(J. H. M.; T. As.)

VERONA, CONGRESS OF, the last of the series of international conferences or congresses based on the principle enunciated in Art. 6 of the treaty of Paris of November 20th, 1815 (see EUROPE, *History*). It met at Verona on the 20th

[1] The view of some scholars is that the original walls were earlier than the time of Gallienus, who reconstructed them on the old lines, taking in, however, the amphitheatre.

of October 1822. The emperor Alexander I. of Russia was present in person. There were also present Count Nesselrode, the Russian minister of foreign affairs; Prince Metternich, representing Austria; Prince Hardenberg and Count Bernstorff, representing Prussia; MM. de Montmorency and Chateaubriand, representing France; and the duke of Wellington, representing Great Britain in place of Lord Londonderry (Castlereagh), whose tragic death occurred on the eve of his setting out to the congress.

In the instructions drawn up by Londonderry for his own guidance, which had been handed to Wellington by Canning without alteration, was clearly defined the attitude of Great Britain towards the three questions which it was supposed would be discussed, viz. the Turkish Question (Greek insurrection), the question of intervention in favour of the royal power in Spain, together with that of the revolted Spanish colonies, and the Italian Question. As regards the latter it was laid down that Great Britain could not charge herself with any superintendence of a system in which she had merely acquiesced, and the duty of the British minister would be merely to keep himself informed, and to see that nothing was done "inconsistent with the European system and the treaties." To make this attitude quite clear, Wellington was further instructed not to hand in his credentials until this question had been disposed of, his place being meanwhile taken by Lord Londonderry (Stewart), Castlereagh's half-brother and successor in the title, who had fulfilled the same function at Troppau and Laibach. In the Spanish Question Wellington was to give voice to the uncompromising opposition of Great Britain to the whole principle of intervention. In the Turkish Question, the probable raising of which had alone induced the British government to send a plenipotentiary to the congress, he was to suggest the eventual necessity for recognizing the belligerent rights of the Greeks, and, in the event of concerted intervention, to be careful not to commit Great Britain beyond the limits of good offices.

The immediate problems arising out of the Turkish Question had, however, been settled between the emperor Alexander and Metternich, to their mutual satisfaction, at the preliminary conferences held at Vienna in September, and at Verona the only question raised was that of the proposed French intervention in Spain. The discussion was opened by three questions formally propounded by Montmorency: (1) Would the Allies withdraw their ministers from Madrid in the event of France being compelled to do so? (2) In case of war, under what form and by what acts would the powers give France their moral support, so as to give to her action the force of the Alliance, and inspire a salutary fear in the revolutionaries of all countries? (3) What material aid would the powers give, if asked by France to intervene, under restrictions which she would declare and they would recognize?

The reply of Alexander, who expressed his surprise at the desire of France to keep the question "wholly French," was to offer to march 150,000 Russians through Germany to Piedmont, where they could be held ready to act against the Jacobins whether in Spain or France. This solution appealed to Metternich and Montmorency as little as to Wellington; but though united in opposing it, four days of "confidential communications" revealed a fundamental difference of opinion between the representative of Great Britain and those of the continental powers on the main point at issue. Wellington, firmly based on the principle of non-intervention, refused to have anything to do with the suggestion, made by Metternich, that the powers should address a common note to the Spanish government in support of the action of France. Finally, Metternich proposed that the Allies should "hold a common language, but in separate notes, though uniform in their principles and objects." This solution was adopted by the continental powers; and Wellington, in accordance with his instructions not to countenance any intervention in Spanish affairs, took no part in the conferences that followed. On the 30th of October the powers handed in their formal replies to the French memorandum. Russia, Austria and Prussia would act as France should in respect of their ministers in Spain, and would give to France every countenance and assistance she might require, the details "being reserved to be specified in a treaty." Wellington, on the other hand, replied on behalf of Great Britain that "having no knowledge of the cause of dispute, and not being able to form a judgment upon a hypothetical case, he could give no answer to any of the questions."

Thus was proclaimed the open breach of Great Britain with the principles and policy of the Great Alliance, which is what gives to the congress its main historical interest.

See *Cambridge Modern Hist.*, chap. i. "The Congresses," by W. Alison Phillips, and for authorities, ibid. p. 787. (W. A. P.)

VERONAL, in medicine, diethylmalonyl urea or diethylbarbituric acid $(C_2H_5)_2C[CO{\cdot}NH]_2CO$, extensively used as a hypnotic. It is prepared by condensing diethylmalonic ester with urea in the presence of sodium ethylate, or by acting with ethyl iodide on the silver salt of malonyl urea; it forms a white crystalline powder, which is odourless, and has a slightly bitter taste. Its introduction followed the investigations of Emil Fischer and J. v. Merling on the pharmacological properties of certain open and closed ureides. Led thereto by the impression that hypnotic action appears to be largely dependent on the presence of ethyl groups, they prepared diethylacetyl urea, diethylmalonyl urea, and dipropylmalonyl urea. All three were found to be hypnotics: the first was about equal in power to sulphonal, whilst the third was four times as powerful, but its use was attended by prolonged after-effects. Veronal was found to be midway. It is best given in cachets (10 to 15 grains). As it does not affect the circulatory or respiratory systems, or temperature, it can be employed in many diseased conditions of the heart and lungs as well as in mental disturbances, acute alcoholism, morphinomania and kidney disease. If taken during a prolonged period it seems to lose its effect. A soluble salt of veronal has been introduced under the name of medinal. Although the toxicity of veronal is low, 135 grains having been taken in a single dose without serious results, the unreasonable consumption by persons suffering from insomnia has led to many deaths, and it has been suggested that the sale should be restricted by the Pharmacy Acts.

VERONICA, ST. According to the most recent version of the legend, Veronica was a pious woman of Jerusalem, who, moved with pity by the spectacle of Jesus carrying His cross to Golgotha, gave Him her kerchief in order that He might wipe the drops of agony from His brow. The Lord accepted the offering, and after using the napkin handed it back to her with the image of His face miraculously impressed upon it. This, however, is not the primitive form of the legend, which a close examination shows to be derived from the following story related by Eusebius in his *Historia Ecclesiastica* (vii. 18). At Caesarea Philippi dwelt the woman whom the Lord healed of an issue of blood (Matt. ix. 20), and at the door of her house stood, on one side a statue of a woman in an attitude of supplication, and on the other side that of a man stretching forth his hand to the woman. It was said that the male figure represented Christ, and that the group had been set up in recognition of the miraculous cure. Legend was not long in providing the woman of the Gospel with a name. In the West she was identified with Martha of Bethany; in the East she was called Berenike, or Beronike, the name appearing in as early a work as the *Acta Pilati*, the most ancient form of which goes back to the 4th century. Towards the 6th century the legend of the woman with the issue of blood became merged in the legend of Pilate, as is shown in the writings known in the middle ages as *Cura sanitatis Tiberii* and *Vindicta Salvatoris*. According to the former of these accounts Veronica, in memory of her cure, caused a portrait of the Saviour to be painted. The emperor Tiberius, when afflicted with a grievous sickness, commanded the woman to bring the portrait to him, worshipped Christ before her eyes, and was cured. The legend continued to gather accretions, and a miraculous origin came to be assigned to the image. It appears that in the 12th century the image began to be identified with one preserved at Rome, and in the popular speech the image, too, was called Veronica. It is interesting to note that the fanciful derivation of the same Veronica from the words *Vera icon* (εἰκών) "true image"—is not, as has been thought, of modern origin, since it occurs in the *Otia Imperialia* (iii. 25) of Gervase of Tilbury (fl. 1211), who says: "Est ergo Veronica pictura Domini vera." In several churches the office of St Veronica, matron, is observed on various dates.

VERRES, GAIUS (*c.* 120–43 B.C.), Roman magistrate, notorious for his misgovernment of Sicily. It is not known to what *gens* he belonged. He at first supported Marius and the popular party, but soon went over to the other side. Sulla made him a present of land at Beneventum, and secured him against punishment for embezzlement. In 80, Verres was quaestor in Asia on the staff of Cn. Cornelius Dolabella, governor of Cilicia. The governor and his subordinate plundered in concert, till in 78 Dolabella had to stand his trial at Rome, and was convicted, mainly on the evidence of Verres, who thus secured a pardon for himself. In 74, by a lavish use of bribes, Verres secured the city praetorship, and, as a creature of Sulla, abused his authority to further the political ends of his party. He was then sent as governor to Sicily, the richest of the Roman provinces. The people were for the most part prosperous and contented, but under Verres the island experienced more misery and desolation than during the time of the first Punic or the recent servile wars. The corn-growers and the revenue collectors were ruined by exorbitant imposts or by the iniquitous cancelling of contracts; temples and private houses were robbed of their works of art; and the rights of Roman citizens were disregarded. Verres returned to Rome in 70, and in the same year, at the request of the Sicilians, Cicero prosecuted him. Verres entrusted his defence to the most eminent of Roman advocates, Q. Hortensius, and he had the sympathy and support of several of the leading Roman nobles. The court was composed exclusively of senators, some of whom might have been his personal friends. But the presiding judge, the city praetor, M'. Acilius Glabrio, was a thoroughly honest man, and his assessors were at least not accessible to bribery. Verres vainly tried to get the trial postponed till 69 when his friend Metellus would be the presiding judge, but in August Cicero opened the case. The effect of the first brief speech was so overwhelming that Hortensius refused to reply, and recommended his client to leave the country. Before the expiration of the nine days allowed for the prosecution Verres was on his way to Massilia. There he lived in exile till 43, when he was proscribed by Antony, the reason alleged being his refusal to surrender some of his art treasures which Antony coveted. Verres may not have been quite so black as he is painted by Cicero, on whose speeches we depend entirely for our knowledge of him, but there can hardly be a doubt that he stood pre-eminent among the worst specimens of Roman provincial governors. Of the seven Verrine orations only two were actually delivered; the remaining five were compiled from the depositions of witnesses, and published after the flight of Verres.

VERRIUS FLACCUS, MARCUS (*c.* 10 B.C.), Roman grammarian and teacher, flourished under Augustus and Tiberius. He was a freedman, and his manumitter has been identified with Verrius Flaccus, an authority on pontifical law; but for chronological reasons the name of Veranius Flaccus, a writer on augury, has been suggested (Teuffel-Schwabe, *Hist. of Roman Lit.* 199, 4). He gained such a reputation by his methods of instruction that he was summoned to court to bring up Gaius and Lucius, the grandsons of Augustus. He removed there with his whole school, and his salary was greatly increased on the condition that he took no fresh pupils. He died at an advanced age during the reign of Tiberius (Suetonius, *De Grammaticis*, 17), and a statue in his honour was erected at Praeneste, in a marble recess, with inscriptions from his *Fasti*. Flaccus was also a distinguished philologist and antiquarian investigator. For his most important work (*De Verborum Significatu*) see FESTUS, SEXTUS. Of the calendar of Roman festivals (*Fasti Praenestini*) engraved on marble and set up in the forum at Praeneste, some fragments were discovered (1771) at some distance from the town itself in a Christian building of later date, and some consular *fasti* in the forum itself (1778). The collection was subsequently increased by two new fragments.

Other lost works of Flaccus were: *De Orthographia: De Obscuris Catonis*, an elucidation of obscurities in the writings of the elder Cato; *Saturnus*, dealing with questions of Roman ritual; *Rerum memoria dignarum libri*, an encyclopaedic work much used by Pliny the elder; *Res Etruscae*, probably on augury.

For the fragments of the *Fasti* see *Corpus Inscriptionum Latinarum*, i. pp. 311, 474; G. Gatti, "Due nuovi Frammenti del Calendario di Verrio Flacco," in *Atti della r. Accademia dei Lincei*, 5th ser., vol. 5, pt. 2, p. 421 (1898); Winther, *De fastis Verrii Flacci ab Ovidio adhibitis* (1885); J. E. Sandys, *Classical Scholarship* (ed. 1906), vol. i., index, *s.v.* "Verrius"; fragments of Flaccus in C. O. Müller's edition of Festus; see also H. Nettleship, *Lectures and Essays*.

VERROCCHIO, ANDREA DEL (1435–1488), Italian goldsmith, sculptor and painter, was born at Florence. He was the son of Michele di Francesco de' Cioni, and took his name from his master, the goldsmith Giuliano Verrocchi. Except through his works, little is known of his life. As a painter he occupies an important position from the fact that Leonardo da Vinci and Lorenzo di Credi worked for many years in his *bottĕga* as pupils and assistants. Only one existing painting can be attributed with absolute certainty to Verrocchio's hand, the celebrated "Baptism of Christ," originally painted for the monks of Vallombrosa, and now in the academy of Florence. The figures of Christ and the Baptist are executed with great vigour and refinement of touch, but are rather hard and angular in style. The two angels are of a much more graceful cast; the face of one is of especial beauty, and Vasari is probably right in saying that this head was painted by the young Leonardo. Other pictures from Verrocchio's *bottĕga* probably exist, as, for example, two in the National Gallery of London formerly attributed to Ant. Pollaiuolo—"Tobias and the Angel" (No. 781) and the very lovely "Madonna and Angels" (No. 296), both very brilliant and jewel-like in colour. This exquisite painting may possibly have been painted from Verrocchio's design by Lorenzo di Credi while he was under the immediate influence of his wonderful fellow-pupil, Da Vinci.[1]

In examining Verrocchio's work as a sculptor we are on surer ground. One of his earliest works was the beautiful marble medallion of the Madonna, over the tomb of Leonardo Bruni of Arezzo in the church of Santa Croce at Florence. In 1472 Verrocchio completed the fine tomb of Giovanni and Piero de' Medici, between the sacristy and the lady chapel of San Lorenzo at Florence. This consists of a great porphyry sarcophagus enriched with magnificent acanthus foliage in bronze. Above it is a graceful open bronze grill, made like a network of cordage. In 1474 Verrocchio began the monument to Cardinal Forteguerra at the west end of Pistoia cathedral. The kneeling figure of the cardinal was never completed, and now lies in a room of La Sapienza, but the whole design is shown in what is probably Verrocchio's original clay sketch, now in the South Kensington Museum. Though this work was designed by Verrocchio, the actual execution of it was entrusted to his assistant, the Florentine Lorenzetto. In 1476 Verrocchio modelled and cast the fine but too realistic bronze statue of David, now in the Bargello (Florence); and in the following year he completed one of the reliefs of the magnificent silver altar-frontal of the Florentine baptistery, that representing the "Beheading of St John." Verrocchio's other works in the precious metals are now lost, but Vasari records that he made many elaborate pieces of plate and jewelry, such as morses for copes, as well as a series of silver statues of the Apostles for the pope's chapel in the Vatican. Between 1478 and 1483 he was occupied in making the bronze group of the "Unbelief of St Thomas," which still stands in

[1] See Crowe and Cavalcaselle, *Painting in Italy* (London, 1864), ii. pp. 400 seq.

one of the external niches of Or San Michele (Florence). He received 800 florins for these two figures, which are more remarkable for the excellence of their technique than for their sculpturesque beauty. The attitudes are rather rigid and the faces hard in expression. Verrocchio's chief masterpiece was the colossal bronze equestrian statue of the Venetian general Bartolommeo Colleoni, which stands in the piazza of SS. Giovanni e Paolo at Venice. Verrocchio received the order for this statue in 1479, but had only completed the model when he died in 1488. In spite of his request that the casting should be entrusted to his pupil Lorenzo di Credi, the work was given to Alessandro Leopardi by the Venetian senate, and the statue was gilt and unveiled in 1496.[1] There appears to be no doubt that the model was completed by Verrocchio himself, and that nothing more than its reproduction in bronze should be attributed to the much feebler hand of Leopardi, who, however, has set his own name alone on the belly-band of the horse—ALEXANDER· LEOPARDVS V. F. OPUS. This is perhaps the noblest equestrian statue in the world, being in some respects superior to the antique bronze of Marcus Aurelius in Rome and to that of Gattamelata at Padua by Donatello. The horse is designed with wonderful nobility and spirit, and the easy pose of the great general, combining perfect balance with absolute ease and security in the saddle, is a marvel of sculpturesque ability. Most remarkable skill is shown by the way in which Verrocchio has exaggerated the strongly marked features of the general, so that nothing of its powerful effect is lost by the lofty position of the head. According to Vasari, Verrocchio was one of the first sculptors who made a practical use of casts from living and dead subjects. He is said also to have produced plastic works in terra-cotta, wood and in wax decorated with colour. As a sculptor his chief pupil was Francesco di Simone, the son of that Simone whom Vasari wrongly calls a brother of Donatello. Another pupil was Agnolo di Polo (Paolo), who worked chiefly in terra-cotta.

Clay sketch for the monument of Cardinal Forteguerra, showing the kneeling portrait of the cardinal, which is not in the actual monument; a very poor modern figure occupies its place.

Verrocchio died in Venice in 1488, and was buried in the church of St Ambrogio in Florence.

VERSAILLES, a town of northern France, capital of the department of Seine-et-Oise, 12 m. by road W.S.W. of Paris, with which it is connected by rail and tram. Pop. (1906) town, 45,246; commune, 54,820. Versailles owes its existence to the palace built by Louis XIV. It stands 460 ft. above the sea, and its fresh healthy air and nearness to the capital attract many residents. The three avenues of St Cloud, Paris and Sceaux converge in the Place d'Armes. Between them stand the former stables of the palace, now occupied by the artillery and engineers. To the south lies the quarter of Satory, the oldest part of Versailles, with the cathedral of St Louis, and to the north the new quarter, with the church of Notre Dame. To the west a gilded iron gate and a stone balustrade shut off the great court of the palace from the Place d'Armes. In this court, which slopes upwards from the gate, stand statues of Richelieu, Condé, Du Guesclin and other famous Frenchmen. At the highest point there is an equestrian statue in bronze of Louis XIV., and to the right and left of this stretch the long wings of the palace, while behind it extend the Cour Royale and the smaller Cour de Marbre, to the north, south and west of which rise the central buildings. The buildings clustered round the Cour de Marbre, which include the apartments of Louis XIV., project into the gardens on the west considerably beyond the rest of the façade. To the north the Chapel Court and to the south the Princes Court, with vaulted passages leading to the gardens, separate the side from the central buildings. On the other is the inscription, "À toutes les gloires de la France," which Louis Philippe justified by forming a collection of works of art (valued at £1,000,000), commemorating the great events and persons of French history. The palace chapel (1696–1710), the roof of which can be seen from afar rising above the rest of the building, was the last work of J. Hardouin-Mansart.

The ground-floor of the north wing on the garden side contains eleven halls of historical pictures from Clovis to Louis XVI., and on the side of the interior courts a gallery containing casts of royal funereal monuments. The Halls of the Crusades open off this gallery, and are decorated with the arms of crusaders and with modern pictures dealing with that period. On the first floor of the north wing on the garden side are ten halls of pictures commemorating historical events from 1795 to 1830; on the court side is the Gallery of Sculpture, which contains the Joan of Arc of the princess Marie of Orleans; and there are seven halls chiefly devoted to French campaigns and generals in Africa, Italy, the Crimea and Mexico, with some famous war pictures by Horace Vernet. The second storey has a portrait gallery. In the north wing is also the theatre built under Louis XV. by Jacques-Ange Gabriel, which was first used on the 16th of May 1770 on the marriage of the dauphin (afterwards Louis XVI.) and Marie Antoinette. Here, on the 2nd of October 1789, the celebrated banquet was given to the Gardes du Corps, the toasts at which provoked the riots that drove the royal family from Versailles; and here the National Assembly met from the 10th of March 1871 till the proclamation of the constitution in 1875, and the Senate from the 8th of March 1876 till the return of the two chambers to Paris in 1879. On the ground-floor of the central buildings are the halls of celebrated warriors (once the anteroom of Madame de Pompadour), marshals, constables and admirals, and the suite of rooms known as the Dauphin's Apartments, now given up to historical portraits. The Galerie Basse, once known as the Gallery of Louis XIII., leads to the rooms surrounding the Marble Court, a series of which contains many plans of battles. The lobbies of the ground-floor are full of busts, statues and tombs of kings and celebrated men. The famous staterooms are on the first floor. On the garden side, facing the north, are a series of seven halls, some of them decorated with tapestries representing the life of Louis XIV. Among them may be mentioned the Hall of Hercules, till 1710 the upper half of the old chapel, where the dukes of Chartres, Maine and Burgundy were married, and Bossuet, Massillon and Bourdaloue preached; the Hall of Mercury, where the coffin of Louis XIV. stood for eight days after his death; and the Hall of Apollo, or throne room. To the front of the palace, facing the west, are the Galleries of War and Peace, with allegorical pictures, and the Glass Gallery, built by Mansart in 1678 (235 ft. long, 35 wide and 42 high), having 34 arches, 17 of which are filled with windows looking on the gardens and 17 with large mirrors. The gallery is overloaded with ornament, and the pictures by Charles Lebrun, the trophies and figures of children by Antoine Coysevox, and the inscriptions attributed to Boileau and Racine, all glorify Louis XIV. This gallery was used by him as a throne room on state occasions. Here the king of Prussia was proclaimed emperor of Germany on the 18th of January 1871. Connected with the Gallery of Peace are the queen's apartments, occupied successively by Marie Thérèse, Marie Leczinska and Marie Antoinette, where the duchess of Angoulême was born, the duchess of Burgundy died, and Marie Antoinette was almost assassinated on the 6th of October 1789. Behind the Glass Gallery on the side of the court are the rooms of Louis XIV. The Œil de Bœuf, named from its oval window, was the anteroom where the courtiers waited till the king rose. In it is a picture representing Louis XIV. and his family as Olympian deities; and it leads to the bedroom in which Louis XIV. died, after using it from 1701, and which Louis XV. occupied from 1722 to 1738. In the south wing of the palace, on the ground-floor, is the Gallery of the Republic and the First Empire, the rooms of which contain paintings of scenes in the life of Napoleon I. A sculpture gallery contains busts of celebrated scholars, artists, generals and public men from the time of Louis XVI. onwards. In the south wing is also the room where the Chamber

[1] See Gay, *Cart. inéd.* i. p. 367.

of Deputies met from 1876 till 1879, and where the Congress has since sat to revise the constitution voted at Versailles in 1875 and to elect the president of the republic. The first floor is almost entirely occupied by the Battle Gallery (394 ft. long and 43 wide), opened in 1836 on the site of rooms used by Monsieur the brother of Louis XIV. and the duke and duchess of Chartres. It is lighted from above, and the walls are hung with pictures of French victories. In the window openings are the names of soldiers killed while fighting for France, with the names of the battles in which they fell, and there are more than eighty busts of princes, admirals, constables, marshals and celebrated warriors who met a similar death. Another room is given up to the events of 1830 and the accession of Louis Philippe, and a gallery contains the statues and busts of kings and celebrities.

The gardens of Versailles were planned by André Le Nôtre. The ground falls away on every side from a terrace adorned with ornamental basins, statues and bronze groups. Westwards from the palace extends a broad avenue, planted with large trees, and having along its centre the grass of the "Tapis Vert"; it is continued by the Grand Canal, 200 ft. wide and 1 m. long. On the south of the terrace two splendid staircases lead past the Orangery to the Swiss Lake, beyond which is the wood of Satory. On the north an avenue, with twenty-two groups of three children, each group holding a marble basin from which a jet of water rises, slopes gently down to the Basin of Neptune, remarkable for its fine sculptures and abundant water. The Orangery (built in 1685 by Mansart) is the finest piece of architecture at Versailles; the central gallery is 508 ft. long and 42 wide, and each of the side galleries is 375 ft. long. There are 1200 orange trees, one of which is said to date from 1421, and 300 other kinds of trees.

The alleys of the parks are ornamented with statues, vases and regularly cut yews, and bordered by hedges surrounding the shrubberies. Between the central terrace and the Tapis Vert is the Basin of Latona or the Frogs, with a white marble group of Latona with Apollo and Diana. Beyond the Tapis Vert is the large Basin of Apollo, who is represented in his chariot drawn by four horses; there are three jets of water, one 60, the others 50 ft. in height. The Grand Canal is still used for nautical displays; under Louis XIV. it was covered with Venetian gondolas and other boats, and the evening entertainments usually ended with a display of fireworks. Around the Tapis Vert are numerous groves, the most remarkable being the Ballroom or Rockery, with a waterfall; the Queen's Shrubbery, the scene of the intrigue of the diamond necklace; that of the Colonnade, with thirty-two marble columns and a group of Pluto carrying off Prosperine, by François Girardon; the King's Shrubbery, laid out in the English style by Louis Philippe; the beautiful Grove of Apollo, with a group of that god and the nymphs, by Girardon; and the Basin of Enceladus, with a jet of water 75 ft. high.

Among the chief attractions of Versailles are the fountains and waterworks made by Louis XIV. in imitation of those he had seen at Fouquet's château of Vaux. Owing to the scarcity of water at Versailles, the works at Marly-le-Roi were constructed in order to bring water from the Seine; but part of the supply thus obtained was diverted to the newly erected château of Marly. Vast sums of money were spent and many lives lost in an attempt to bring water from the Eure, but the work was stopped by the war of 1688. At last the waters of the plateau between Versailles and Rambouillet were collected and led by channels (total length 98 m.) to the gardens, the soil of which covers innumerable pipes, vaults and aqueducts.

Beyond the present park, but within that of Louis XIV., are the two Trianons. The Grand Trianon was originally erected as a retreat for Louis XIV. in 1670, but in 1687 Mansart built a new palace on its site. Louis XV., after establishing a botanic garden, made Gabriel build in 1766 the small pavilion of the Petit Trianon, where the machinery is still shown by which his supper-table came up through the floor. It was a favourite residence of Marie Antoinette, who had a garden laid out in the English style, with rustic villas in which the ladies of the court led a mimic peasant-life. The Grand Trianon is a one-storeyed building with two wings, and has been occupied by Monsieur (Louis XIV.'s brother), by the Great Dauphin, Napoleon I., and Louis Philippe and his court. The gardens of the Grand Trianon are in the same style as those of Versailles, and there is a museum with a curious collection of state carriages, old harness, &c.

Apart from the palace, there are no buildings of interest in Versailles; the church of Notre Dame, built by Mansart, the cathedral of St Louis, built by his grandson, the Protestant church and the English chapel being in no way remarkable. The celebrated tennis-court (Jeu de Paume) is now used as a museum. The large and sumptuous palace of the prefecture was built during the second empire, and was a residence of the president of the republic from 1871 to 1879. The library consists of 60,000 volumes; and the military hospital formerly accommodated 2000 people in the service of the palace. There are statues of General Hoche and of Abbé de l'Épée in the town. A school of horticulture was founded in 1874, attached to an excellent garden, near the Swiss Lake.

Versailles is the seat of a bishopric, a prefect and a court of assizes, and has tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a branch of the Bank of France, and, among its educational establishments, lycées and training colleges for both sexes and a technical school. It is an important garrison town and has a school of military engineering and artillery. Distilling, boot and shoe making, and market-gardening employ many of the people, but the town has no specially characteristic industry. The links of the Paris Golf Club are at La Boulie near Versailles.

Louis XIII. often hunted in the woods of Versailles, and built a small pavilion at the corner of what is now the rue de la Pompe and the avenue of St Cloud. In 1627 he entrusted Jacques Lemercier with the plan of a château. In 1661 Louis Levau made some additions which were further developed by him in 1668. In 1678 Mansart took over the work, the Galerie des Glaces, the chapel and the two wings being due to him. In 1682 Louis XIV. took up his residence in the château. It is estimated that 20 million pounds were spent on the palace, gardens and works of art, the accounts for which were destroyed by the king. Till his time the town was represented by a few houses to the south of the present Place d'Armes; but land was given to the lords of the court and new houses sprang up, chiefly in the north quarter. Under Louis XV. the parish of St Louis was formed to the south for the increasing population, and new streets were built to the north on the meadows of Clagny, where in 1674 Mansart had built at Louis XIV.'s orders a château for Madame de Montespan, which was now pulled down. Under Louis XVI. the town extended to the east and received a municipality; in 1802 it gave its name to a bishopric. In 1783 the armistice preliminary to the treaty of peace between Great Britain and the United States was signed at Versailles. The states-general met here on the 5th of May 1789, and on the 20th of June took the solemn oath in the Tennis Court by which they bound themselves not to separate till they had given France a constitution. Napoleon neglected, and Louis XVIII. and Charles X. merely kept up, Versailles, but Louis Philippe restored its ancient splendour at the cost of £1,000,000. In 1870 and 1871 the town was the headquarters of the German army besieging Paris. After the peace Versailles was the seat of the French National Assembly while the commune was triumphant in Paris, and of the two chambers till 1879, being declared the official capital of France.

See A. P. Gille, *Versailles et les deux Trianons*, with illustrations by M. Lambert (Tours, 1899, 1900); P. de Nolhac, *La Création de Versailles* (Versailles, 1901); J. E. Farmer, *Versailles and the Court under Louis XIV.* (New York, 1905).

VERS DE SOCIÉTÉ, a term for social or familiar poetry, which was originally borrowed from the French, and has now come to rank as an English expression (see Fennell, *The Stamford Dictionary of Anglicised Words*). The use of the phrase as an English one is first met with at the opening of the 19th century. It is to be observed that it has come to bear a meaning which is not wholly equivalent to that of the French original. It was said of the blind philosopher, M. C. J. Pougens (1755–1833), that his *petits vers de société* procured great success for him in the *salons* of Paris, and several of the rhymesters of the early 18th century were prominent for their adroitness in composing *petits vers sur des sujets légers*. The prince of such graceful triflers was the Abbé de Chaulieu (1639–1720), of whom it was said that he made verses solely for the amusement of his friends, and without the smallest intention of seeing them in print. The best of his effusions have preserved a certain freshness because of the neatness with which they are turned, but it can scarcely be said that they have any pretension to be called poetry. . They were inspired by incidents in the private life of the day, and were largely addressed to a few friends of exalted rank, who were hardly less witty than the author himself, such as the duc de Nevers, the marquis de Lassay, the duchesse de Bouillon and the marquis de la Fare. In the collections of Chaulieu's works, which were very often reprinted, side by side with his own pieces will be found *petits vers de société* indited by these great friends of his, and often quite as well turned as his own. To write such verses, indeed, was almost an accomplishment of good breeding. An enormous collection of them was brought together by Titon du Tillet (1676–1762), in his *Parnasse françois*, where those who are curious on the subject may observe to satiety how ingenious and artificial and trifling the *vers de société* of the French 18th century could be. The fashion for them followed upon the decline of an interest in rondeaux, ballades and villanelles, and Chaulieu himself had not a little to do with throwing those ingenuities out of fashion, his attack on Benserade, who went so far as to turn the whole of Ovid's *Metamorphoses* into rondeaux, being, according to his editor of 1732, "the first work which displayed the delicacy of the Abbé de Chaulieu's taste, and his talent for poetry." Of the writers of *vers de société* in France, J. B. Rousseau had the most poetical faculty; he was, in fact, a poet, and he wrote a "Billet à Chaulieu" which is a gem of delicate and playful charm. But, as a rule, the efforts of the French versifiers *dans les petits genres* were not of considerable poetic value.

If in England the expression *vers de société* carries with it more literary dignity, this is mainly due to the genius of one man. Prior's *Poems on Several Occasions*, collected in 1709, presents us with some of the earliest entirely characteristic specimens of *vers de société*, and with some of the best. Here the poet consciously, and openly, resigns the pretension of high effort and an appeal to Parnassus. He is paying a visit at Burghley House, where the conversation turns on the merits and adventures of Mr Fleetwood Shepherd; Prior then and there throws off, in extremely graceful verse, a piece appropriate to the occasion. He addresses it, and he dates it (May 14, 1689); and this is a typical example of *vers de société*. It will be seen that Prior, who learned much from his residence in the heart of the French world of fashion between 1711 and 1715, treats very much the same subjects as Chaulieu and La Fare were treating, but he does so with more force of style and dignity of imagination. As the 18th century progressed, the example of Prior was often followed by English poets, without, however, any general recapture of his forcible grace. The *vers de société* tended to be merged in the epistle and in the epigram. Swift, however, when he was neither coarse nor frigid, sometimes achieved a genuine success, as in the admirable verses on his own death. The odes of Ambrose Philips (1671–1749) addressed by name to various private persons, and, most happily, to children, were not understood in his own age, but possess some of the most fortunate characteristics of pure *vers de société*. In his "Welcome from Greece," a study in *ottava rima*, Gay produced a masterpiece in this delicate class, but most of his easy writings belong to a different category. Nothing of peculiar importance detains us until we reach Cowper, whose poems for particular occasions, such as those on "Mrs Throckmorton's Bullfinch" and "The Distressed Travellers," are models of the poetic use of actual circumstances treated with an agreeable levity, or an artful naïveté. In a later age, Byron, who excelled in so many departments of poetry, was an occasional writer of brilliant *vers de société*, such as the epistle "Huzza, Hodgson," but to find a direct successor to Prior it is necessary to pass Henry Luttrell (1765–1851) and W. R. Spencer (1769–1834), and to come down to W. M. Praed (*q.v.*). A certain character was given to English *vers de société* by Hood and Barham, but the former was too much addicted to a play upon words, the latter was too boisterous, to be considered as direct continuers of the tradition of Prior. That tradition, however, was revived by Frederick Locker, afterwards Locker-Lampson (1821–1895), whose *London Lyrics*, first printed in 1857 and constantly modified until 1893, is in some respects the typical modern example of pure *vers de société*. Locker was a simple, clear and easy writer; he successfully avoided the least appearance of that effort which is fatal to this kind of verse. His "Rotten Row," with its reminiscences of the early sixties,

> "But where is now the courtly troop
> That once rode laughing by?
> I miss the curls of Cantelupe,
> The laugh of Lady Di,"—

touches of real portraiture—is a perfect example of *vers de société*. Since the days of Locker, those who have attempted to strike the lighter lyre in English have been very numerous. Almost immeasurably superior to the rest has been Mr Austin Dobson, who is, however, something more than a writer of *vers de société*.

Collections of *vers de société* of much excellence have been published by J. K. Stephen (1859–92), Andrew Lang (b. 1844), A. D. Godley (b. 1856), Owen Seaman (b. 1861) and A. R. Ropes ("Adrian Ross") (b. 1859). (E. G.)

VERSE (from Lat. *versus*, literally a line or furrow drawn by turning the plough, from *vertere*, and afterwards signifying an arrangement of syllables into feet), the name given to an assemblage of words so placed together as to produce a metrical effect. The art of making, and the science of analysing, such verses is known as Versification. According to Max Müller, there is an analogy between *versus* and the Sanskrit term, *vritta*, which is the name given by the ancient grammarians of India to the rule determining the value of the quantity in vedic poetry. In modern speech, verse is directly contrasted with prose, as being essentially the result of an attention to determined rules of form. In English we speak of "a verse" or "verses," with reference to specific instances, or of "verse," as the general science or art of metrical expression, with its regulations and phenomena. A verse, which is a series of rhythmical syllables, divided by pauses, is destined in script to occupy a single line, and was so understood by the ancients (the στίχος of the Greeks). The Alexandrian scholiast Hephaestion speaks distinctly of verses that ceased to be verses because they were too long; he stigmatizes a pentameter line of Callimachus as στίχον ὑπέρμετρον. There is no danger, therefore, in our emphasizing this rule, and in saying that, even in Mr Swinburne's most extended experiments the theory is that a verse fills but one line in a supposititious piece of writing.

It is essential that the verse so limited should be a complete form in itself. It is not, like a clause or a sentence in prose, unrecurrent and unlimited, but it presents us with a successive and a continuous cadence, confined within definite bounds. There has been a constant discussion as to what it is in which this succession and this continuity consist, and here we come at once to the principal difficulty which makes the analysis of the processes of the poets so difficult. To go back to the earliest European tradition, it is universally admitted that the ancient Greeks considered the art of verse as a branch of music, and as such co-ordinated it with harmony and orchestral effect. This appears from definite statements preserved in the fragments of Aristoxenus of Tarentum, a grammarian who lived in the age of Alexander the Great, and whom we shall see to have been the first who laid down definite laws for prosody as a department of musical art (μουσική). It was found necessary, in order to compose a work of musical value, to work out a system of disciplined and linked movement. This system, or arrangement, was called rhythm, and this is common to all the arts of melody. Harmony, consisting in the reproduction of the sound of human voices or of musical instruments, and orchestrics, dealing with the movements of the human body, were expressed in metrical art by that arrangement of syllables which is known as rhythm. The science of metre is the teaching of those laws on which depends the rhythmical forms of poetry. This science has been, from the earliest ages of criticism, divided into a study of the general principles upon which all these forms are builded, and upon the special types into which they have gradually developed.

In considering ancient versification, it is necessary to give attention to Latin as well as to Greek metre, because although the Roman poets were in the main dependent upon the earlier tradition, there were several points at which they broke away, and were almost entirely independent. Roman verse, though essentially the same as Greek verse, was modified by the national development of Italian forms of poetry, by a simplified imitation of Greek measures, and by a varied intensity in the creation of new types of the old Greek artistic forms (Volkmann). In later times there was a tendency to consider the laws of metre as superior to, and almost independent of, the native impulse of the poet; and this is where the study of the old poetry itself is most salutary, as checking us in our tendency to bow too slavishly to the rules of the grammarians. No doubt, in the archaic times, theory and practice went hand in hand. The poet, held in constant check by the exigencies of music, was obliged to recognize the existence of certain rules, the necessity of which was confirmed by the delicacy of his ear. These he would pass down to his disciples, with any further discoveries which he might himself have made. For instance, what we are somewhat vaguely told of the influence of a poet like Archilochus, to whom the very invention of trochaic and iambic metre is, perhaps fabulously, attributed, points to the probability that in Archilochus the Ionian race produced a poet of extraordinary daring and delicacy of ear, who gathered the wandering rhythms that had existed, and had doubtless been used in an uncertain way before his time, into a system which could be depended upon, and not in his hands only, to produce certain effects of welcome variety. His system would engage the attention of theorists, and we learn that by the time of Plato schools of oral metrical education were already in existence, where the science of sounds and syllables was already beginning to be recognized, as may be seen in the *Cratylus*. Before long, the teachings in these peripatetic schools would be preserved, for safety's sake, in writing, and the theoretic literature of versification would begin. In fact, we read in Suidas of a certain Lasus of Hermione who wrote an *Art of Poetry*, and the age of this, the earliest of recorded authorities on the formal laws of verse, is fixed for us by the fact that he is spoken of as having been the master of Pindar. Of the writings of Lasus and his followers, however, nothing remains, and the character of their teaching is problematical. In the 3rd century B.C., however, we come upon a figure which preserves a definite character; this is Aristoxenus, the disciple of Aristotle, who gave his undivided attention to rhythm, and who lives, unfortunately only in fragments, as the most eminent musical critic of antiquity. The brief fragments of his *Elements of Rhythm* (ῥυθμικὰ στοιχεῖα), originally written in three books, are of unsurpassed value to us as illustrating the attitude of classical Greece to the interrelation of verse and music. The third book of Aristoxenus dealt specifically with λέξις, or the application of rhythm to artistically composed and written verse.

It is certain that, after the time of Alexander the Great, the theories of verse tended somewhat rapidly to release themselves from the theories of music, and when, in the successive ages of Greek criticism, much attention was given to the laws of versification, less and less was said about harmony and more and more about metre. Rules, often of a highly arbitrary nature, were drawn up by grammarians, who founded their laws on a scholiastic study of the ancient poets. The majority of the works in which these rules were collected are lost, but an enchiridion of Greek metres, by Hephaestion, a scholiast of the 2nd century A.D., has been preserved. First printed in 1526, editions and translations of Hephaestion's manual have not been infrequent.

It is from Hephaestion that most of our ideas on the subject of classical prosody are obtained. His work, as we possess it, seems to be a summary, made by himself, for use in schools, of an exhaustive treatise he had published on the Greek metrical system as a whole, in 48 books. The pre-eminent importance of Hephaestion was exposed to the learned world of Europe by Th. Gaisford, in 1810. A contemporary of Hephaestion, Herodian, who was one of the most eminent of Alexandrian grammarians, gave close attention to prosody, and was believed to have summed up everything that could be known on the subject of verse by critics of the 2nd century A.D., in his Μεγάλη προσῳδία, in twenty books. As Herodian, throughout his life, seems to have concentrated his attention on the study of Homer, it is supposed that he started with a consideration of the metre and accent of the *Iliad*. The almost complete loss of his treatises is regrettable. Philoxenus was the author of a very early work, Περὶ μέτρων; but this is entirely lost. In the musical cyclopaedia of Quintilian, there was included a chapter on the elements of the rhythmic art, and in this the metres recognized at the time were recorded and described. Among the Latin authorities on versification, the leading place is taken, in the 1st century B.C., by Terentius Varro, whose systematic treatment of metre in his works *De sermone latino* and *De lingua latina* is often referred to. But we know more of Terentianus Maurus, who flourished in the second half of the 2nd century A.D., since we possess from his hand a handbook to metre, written in verse, in which, in particular, the Horatian metres are carefully analysed. He follows Caesius Bassus, the friend of Nero, who had dedicated to his imperial patron a work on prosody, of which fragments exist. Three tracts, attributed to the rhetor C. Marius Victorinus (one entitled *De ratione metrorum*), belong to the 4th century, and are still quoted by scholars. Another early authority was Flavius Mallius Theodorus, whose *De Metris* has been frequently reprinted.

The metrical theory of the Byzantine grammarians was entirely in unison with the old tradition of the Alexandrian schools, and depended on the authority of Hephaestion. Michael Psellus, in the 9th century, wrote abundantly on the subject, and towards the close of the Empire the verse-handbooks of Isaac Tzetzes (d. 1138) and of his brother Joannes were in general use. A large number of other Byzantine scholiasts and theorists are mentioned in this connexion by Gleditsch. Very little attention was paid to metrical science in medieval and even Renaissance days. It is much to the honour of English scholarship that the earliest modern writer who made a rational study of ancient metre was Richard Bentley, in his *Schediasma de metris Terentianis*, printed at Cambridge in 1726. He was soon followed by the Germans, in particular by Hermann, Boeckh and J. A. Apel. To this day, German scholarship easily leads in the rational and accurate study of classical versification.

The chief principle in ancient verse was quantity, that is, the amount of time involved in the effort to express a syllable. Accordingly, the two basal types which lie at the foundation of classical metre are "longs" and "shorts." The convention was that a long syllable was equal to two short ones: accordingly there was a real truth in calling the succession of such "feet" metre, for the length, or weight, of the syllables forming them could be, and was, measured. What has to be realized in speaking of ancient metre is that the value of these feet was defined with exactitude, not left uncertain, as it is in modern European verse, when accent is almost always made the guiding principle. In Greek verse, there might be an *ictus* (stress), which fell upon the long syllable, but it could only be a regulating element, and accent was always a secondary element in the construction of Greek metre. The "feet" recognized and described by the ancient grammarians were various, and in their apparent diversity sometimes difficult to follow, but the comprehension of them is simplified if the student realizes that the names given to them are often superfluous. The main distinction between feet consists in the diversity of the relation between the strong and the weak syllables. There are naturally only two movements, the quick and the slow. Thus we have the anapaest (⏑ ⏑ —, short-short-long) and the dactyl (— ⏑ ⏑, long-short-short), which are equal, and differ only as regards the position of their parts. To these follow two feet which must be considered as in their essence non-metrical, as it is only in combination with others that they can become metrical. These are the spondee (— —, long-long) and the pyrrhic (⏑ ⏑, short-short). Of more essential character are the two descriptions of slow feet, the iamb (⏑ —, short-long) and the trochee (— ⏑, long-short). Besides these definite types, the ingenuity of formalists has invented an almost infinite number of other "feet." It is, perhaps, necessary to mention some of the principal of these, although they are, in the majority of cases, purely arbitrary. In the rapid measures we find the tribrach (⏑⏑⏑, short-short-short), the molossus (———, long-long-long), the amphibrach (⏑—⏑, short-long-short), the amphimacer (—⏑—, long-short-long), the bacchius (⏑——, short-long-long) and the antibacchius (——⏑, long-long-short). There is a foot of four syllables, the choriamb (—⏑⏑—, long-short-short-long), which is the fundamental foot in Aeolic verse—very frequently mentioned, but very seldom met with.

It must not be forgotten that the prosodical terminology of the Greeks, which is often treated by non-poetical writers as something scientific and even sacrosanct, dates from a time when ancient literature had lost all its freshness and impulse, and was exclusively the study of analysts and grammarians. Between the life of Pindar, for instance, and that of Hephaestion, the great metrical authority, there extends a longer period than between Chaucer and Professor Skeat; and to appreciate the value of the rules of Greek prosody we must recollect that those rules were invented by learned and academic men to account for phenomena which they observed, and wished to comprehend, in writings that had long been classical, and were already growing positively archaic. The fact seems to be that the combination of long and short syllables into spondees, iambs, dactyls and anapaests, forms the sole genuine basis of all classical verse.

Metre is a science which pays attention to all the possible regular arrangements which can be made of these four indispensable and indestructible types. Of the metres of the ancients by far the most often employed, and no doubt the oldest, was the dactylic hexameter, a combination of six feet, five successive dactyls and a spondee or trochee:—

/⏑⏑ /⏑⏑ /⏑⏑ /⏑⏑ /⏑⏑ /⏑

This was known to the ancients as "epic" verse, in contrast to the various lyrical measures. The poetry of Homer is the typical example of the use of the epic hexameter, and the character of the Homeric saga led to the fashion by which the dactylic hexameter, whatever its subject, was styled "heroic metre." The earliest epics, doubtless, were chanted to the accompaniment of a stringed instrument, on which the pulsation of the verse (ἔπη) was recorded. It was the opinion of W. Christ that the origin of the hexameter was to be sought in hieratic poetry, the fulness of the long dactylic line attracting the priests to its use in the delivery of oracles, from which it naturally passed to solemn tales of the actions of gods and heroes. It is more difficult to see how, later on, it became the vehicle for comic and satiric writing, and is found at last adopted by the bucolic poets for their amorous and pastoral dialogues. The Homeric form of the dactylic hexameter has been usually taken, and was taken in classical times, as the normal one, but there have been many variations. A hexameter found in Catullus consists exclusively of spondees, and deviation from the original heroic type could go no further. This concentration of heavy sounds was cultivated to give solemnity to the character of the line. In the whole matter, it is best to recognize that the rules of the grammarians were made after the event, to account for the fact that the poets had chosen, while adhering to the verse-structure of five rapid beats and a subsidence, to vary the internal character of that structure exactly as their ear and their passion dictated. This seems particularly true in the case of the caesura, where the question is not so much a matter of defining "male" caesura or "female" caesura, "bucolic" caesura or "trochaic," as of patiently noting instances in which the unconscious poet, led by his inspiration, has varied his pauses and his emphasis at his own free will. The critics have written much of "prosodical licence," but verse in the days of Homer, like verse now, is simply good or bad, and if it is good it may show liberty and variety, but it knows nothing of "licence."

We pass, by a natural transition, to the pentameter, which is the most frequently employed of what are known as the syncopied forms of dactylic verse. It was used with the hexameter, to produce the effect which was early called elegiac, and its form shows the appropriateness of this custom:—

"Cynthia | prima fu- | it, || Cynthia | finis e- | rit."

A hexameter, full of energy and exaltation, followed by a descending and melancholy pentameter, had an immediate tendency to take a complete form, and this is the origin of the stanza. The peculiar character of this two-line stanza has been fixed for all time by a brilliant epigram of Schiller, which is itself a specimen of the form:—

"Im Hexameter steigt des Springquells flüssige Säule,
Im Pentameter drauf fällt sie melodisch herab."

Such a distich was called an elegy, ἐλεγεῖον, as specially suitable to an ἔλεγος or lamentation. It is difficult to say with certainty whether the distich so composed was essential as an accompaniment to flute-music in the earliest times, or how soon there came to be written purely literary elegies towards which the melody stood in a secondary or ornamental relation. It has, however, been observed that even when the distich had obviously come to be a purely intellectual or lyrical thing, there remained in the sound of the pentameter the trace of lamentation, in which its primitive use at funeral services was clearly preserved. Other grammarians, however, among whom Cäsar, in his work on the origin of elegiac verse, is prominent,—do not believe in the lugubrious essence of the pentameter, and think that the elegiacal couplet was originally erotic, and was adapted to mournful themes by Simonides. If we may credit a passage in Athenaeus, it would seem that the earliest-known elegists, such as Callinus and Solon, wrote for recitation, pure and simple, without the accompaniment of any instrument.

Trochaic verse is called by the ancient grammarians headless (ἀκέφαλον), because it really consists of iambic verse deprived of its head, or opening syllable. The iambic measure (⏑—⏑—⏑—) becomes trochaic if we cut off the first "short," and make it run —⏑—⏑—⏑—. The pure trochaic trimeter and tetrameter had a character of breathless speed, and sometimes bore the name of choric (ῥυθμὸς χορεῖος), because it was peculiarly appropriate to the dance, and was used for poems which expressed a quickly stepping sentiment. It is understood that, after having been known as a musical movement, it was first employed in the composition of poetry by Archilochus of Paros, in the 7th century B.C.

Iambic metre was, next to the dactylic hexameter, the form of verse most frequently employed by the poets of Greek antiquity. Archilochus, again, who seems to have been a great initiator in the arts of versification, is credited with the invention of the iambic trimeter also, but it certainly existed before his time. Murray believes the original iambic measure, in its popular familiarity, to have sprung from the worship of the homely peasant gods, Dionysus and Demeter. It was not far removed from prose; it gave a writer opportunity for expressing popular thoughts in a manner which simple men could appreciate, being close to their own unsophisticated speech. In particular, it presented itself as a heaven-made instrument for the talent of Euripides, "who, seeing poetry and meaning in every stone of a street, found in the current iambic trimeter a vehicle of expression in some ways more flexible even than prose."

It was not, however, until the invention of the lyric proper, whether individual to the poet, or choral, that the full richness of possible rhythms became obvious to the Greeks. The lyric inspiration came originally from the island of Lesbos, and it passed down through the Asiatic archipelago to Crete before it reached the mainland of Greece. The Lesbians cultivated a monodic ode-poetry in strophes and monostrophes, the enchanting beauty of which can still be realized in measure from what remains to us of the writings of Sappho and Alcaeus There is a stanza known as the Sapphic and another as the Alcaic.

The Sapphic runs as follows:—

—́ ◡ — ⏒ | —́ ◡ ◡ — | ◡ —. ⏓
—́ ◡ — ⏒ | —́ ◡ ◡̇ — | ◡ —. ⏓
—́ ◡ — ⏒ | —́ ◡ ◡ — | ◡ — ⏓
— ◡ ◡ | — —

The stanza of Alcaeus runs:—

⏒ — ◡ —́ | ⏒ — ◡ ◡ | — ◡ —́
⏒ — ◡ —́ | ⏒ — ◡ ◡ | — ◡ —́
⏒ — ◡ —́ | ⏒ — ◡ — | —, — ◡ ◡
— ◡ ◡ —́ | ◡ —. —

These marvellous inventions suited the different moods of these strongly contrasted lyrists, the "violet-crowned, pure, softly smiling Sappho," and the fiery, vehement soldier who was Alcaeus. We must give them peculiar attention, since they were the two earliest models for the lyric passion which has since then expressed itself in so many stanzaic forms, but in none of so faultless a perfection as the original Lesbian types.

The name of Stesichorus of Himera points to the belief of antiquity that he was the earliest poet who gave form to the choral song; he must have been called the "choir-setter" because he arranged and wrote for choirs semi-epic verse of a new kind, "made up of halves of the epic hexameter, interspersed with short variations—epitrites, anapaests or mere syncopae—just enough to break the dactylic swing, to make the verse lyrical" (Gilbert Murray). But it appears to be to Arion that the artistic form of the dithyramb is due. We are all among innovators and creators in this glorious 5th century B.C. Simonides gathered the various inventions together, and exercised his genius upon them all: he was the earliest universal lyrist of the world: he treated the styles of verse, as Shelley or as Victor Hugo did, with an impartial mastery.

After the happy event of the Persian War, Athens became the centre of literary activity in Greece, and here the great school of drama developed itself, using for its vehicle, in dialogue, monologue and chorus, nearly all the metres which earlier ages and distant provinces had invented. The verse-form which the dramatists preferred to use was almost exclusively the iambic trimeter, a form which adapted itself equally well to tragedy and to comedy. Aeschylus employed for his choruses a great number of lyric measures, which Sophocles and Euripides reduced and regulated. With the age of the dramatists the creative power of the Greeks in versification came to an end, and the revival of poetic enthusiasm in the Alexandrian age brought with it no talent for fresh metrical inventions, and the time had now arrived when the harvest of Greek prosody was completely garnered.

Latin Metre.—Very little is known about the verse-forms of the original inhabitants of Italy, before the introduction of Greek influences. The earliest use of poetry as a national art in Italy is to be judged by inscriptions in what is called the Saturnian metre. Already, the first Latin epic poets, Livius Andronicus in his *Odyssia*, Naevius in his *Bellum Punicum*, the Scipios in their *Elogia*, combined their rude national sense of folk-song with a consciousness of the quantitative rules of the Greeks. But the same writers, in their dramas, undoubtedly used Greek metres without adaptation, and it is therefore likely that the ancient Saturnian measure was already looked upon as barbarous, and it makes no further reappearance in Latin literature (cf. Gleditsch). The introduction of Greek dramatic metre marks the start of regular poetry among the Latins, which was due, not to men of Roman birth, but to poets of Greek extraction or inhabiting the Greek-speaking provinces of Italy. These writers, bearing the stamp of a widely recognized cultivation, threw the old national verse back into oblivion. Latin verse, then, began in a free but loyal modification of the principles of Greek verse. Plautus was particularly ambitious and skilful in this work, and, aided by a native genius for metre, he laid down the basis of Latin dramatic versification. Terence was a feebler and at the same time a more timid metrist. In satire, the iambic and trochaic measures were carefully adapted by Ennius and Lucilius. The dactylic hexameter followed, and Ennius, in all matters of verse a daring innovator, directly imitated in his *Annales* the epic measure of the Greeks. To him also is attributed the introduction of the elegiac distich, hexameter and pentameter. The dactylic hexameter was forthwith adopted as the leading metre of the Roman poets, and, as Gleditsch has pointed out, the basis upon which all future versification was to be erected was firmly laid down before the death of Ennius in 169 B.C. Lucilius followed, but perhaps with some tendency to retrogression, for the Latin critics seem to have looked upon his metre as wanting both in melody and elasticity. Lucretius, on the other hand, made a further advance on the labours of Ennius, in his study of

"the rise
And long roll of the Hexameter."

Lest, however, this great form of verse should take too exclusive a place in the imagination of the Romans, a younger generation, with Laevius and Terentius Varro at their head, began to imitate the lyrical measures of the Greeks with remarkable success. Varro, who has been styled the earliest metrical theorist of Rome, opened up a new field in this direction by the example of his Menippean satires. These poets left the rigid school of Ennius, and sought to emulate the Alexandrians of their own age: we see the result in the lyric measures used so gracefully and with such brilliant ease by Catullus. The versification of the Romans reached its highest point of polish in the Augustan age, in the writings of Tibullus, Propertius, Virgil and particularly Ovid, who is considered to mark the highest level of various excellence which has ever been reached by a master of Latin versification. In Horace has been traced a tendency to archaism in the study of verse, and in his odes and epodes he was not content with the soft Alexandrian models, but aimed at achieving more vigorous effects by an imitation of the older Greek models, such as Alcaeus and even Archilochus. After the Augustan age, it was no longer the Greek poets, ancient or recent, who were imitated, but the Augustans themselves were taken as the inapproachable models of Roman verse.

We have hitherto spoken of classical versification as it was regarded by those whom, without offence, we may describe as pedants. But there is precious evidence of the mode in which metre was regarded by poets, and by one of the greatest artists of antiquity. In his *Art of Poetry* Horace has been speaking of the need of method in composition—"tantum series juncturaque pollet"—and this reminds him that he has said nothing of the art of verse. The succeeding twenty-four lines contain all that this great poet thought it needful to supply on the subject with which Alexandrian grammarians could fill as many volumes. Although he is actually writing in dactylic hexameters, he does not mention this form of verse; he is chiefly occupied in describing, rather unscientifically, the iambic trimeter, and in praising the iamb, *pes citus*. He applauds, still somewhat vaguely, the stately versification of the precursors, Ennius and Accius, and blames the *immodulata poemata* of careless modern writers, whose laxity is condoned by popular ignorance. The only way to escape such faults is to study the Greeks by night and by day, but Horace evidently means by his *exemplaria Graeca*, not the scholiasts with their lists of metres and their laborious rules, but the old poets with their fine raptures. On Italian ground he points to Plautus, and laments that the Romans of his own day, fascinated by softer cadences, have lost their veneration for the vigorous beauty of the *Plautinos numeros*. And Horace closes with a queer suggestion, which may be taken as we please, that a poet in an age of flagging inspiration must trust to his fingers as well as his ears.

Modern Versification.—The main distinction between classical and modern versification consists in the negligence shown by the moderns to *quantity*, which is defined as the length or shortness of the sound of syllables, as determined by the time required to pronounce them. This dimension of sound was rigid in the case of Greek and Latin poetry, until, in what is known as the

Middle Greek period, there came in a general tendency to relax the exact value of sounds and syllables, and to introduce *accent*, which is a measure of quality rather than of quantity. A syllable, in modern verse, is heavy or light, according as it is accented or unaccented—that is to say, according as it receives stress from the voice or not. In the word "tulip," for instance, the syllables are of equal length, but the accent is strongly upon the first. It is mainly a question of force with us, not of time as with the ancients. There is, however, an element of quantity in modern verse, as there was of accent in ancient verse. The foot, in modern verse, takes a less prominent place in itself than it did in Greece, and is regarded more in relation to the whole line of which it makes a part. A mere counting of syllables is useless. In Milton's

"From haunted spring and dale,
Edg'd with poplar pale,"

an ancient scholiast would have found it impossible to discover any harmony, for he would have had no means of measuring the value of the heavy accent on "edg'd," followed by a pause, and would have demanded another syllable in the second line to turn the whole into verse. The first poet to whom it occurred that it was needless to attach such predominant importance to quantity was Gregory of Nazianzen (d. 389), a Christian bishop of the Greek Church. In two important poems by Gregory all prosodical discipline is found to have disappeared, and the rule of verse has come to be accentual, with a heavy stress on the penultimate syllable. About the same time, the Greek fabulist Babrius employed a choliambic metre having a strong accent on the penultimate. The poets of the transition loved to cultivate a loose iambic trimeter in twelve syllables, and shorter octosyllabic forms called "anacreontic," although they were far enough from repeating the splendid effects of Anacreon. In these the old laws of quantity were more and more generally superseded by stress, and in all this we may see the dawn of the free accentual versification of modern Europe.

Romance Languages.—The prosodies of Provence, France, Italy and Spain were derived from the decayed and simplified forms of Latin verse by a slow and sometimes almost intangible transition. In these modern metres, however, when they came to be independent, it was found that all syllables in the line were of equal value, and that the sole criterion of measure was the number of these in each case. The relics of ancient versification, deprived of all the regulated principles of rhythmical art, received in return the ornament of obligatory and difficult rhyme, without which the weak rhythm itself would practically have disappeared. A new species of rhythm, depending on the varieties of mood, was introduced, and stanzaic forms of great elaboration and beauty were invented. The earliest standard work which exhibits in full the definitions of Romance versification is the *Leys d'Amors* of an unknown Provençal grammarian, written in 1356.[1] Another medieval treatise of great importance is the *De Vulgari Eloquentia*, written by Dante in 1304. There is this difference between these two works, that the former, written long after the flourishing period of the troubadours, analyses what has been accomplished in the past, while the other, standing at the starting-point of Italian poetry, describes what has to be done in the future. Both of these authorities quote the ten-syllable line of five equal feet as most to be admired and as forming the basis of poetry. But the octosyllabic, almost in the earliest times, became a main favourite with the poets, and may be said to be the most frequently used of all lyrical measures in medieval Romance poetry. The earliest specimen of all, however, a mere refrain excepted, is the fragment of the Provençal "Boethius," and this is decasyllabic, like all French poems of the Charlemagne cycle. The typical French heroic verse, the alexandrine of six feet, is not found in the old epic poetry. In Provençal and early French the position of the caesura in each line was fixed by strict rules; in Italian these were relaxed. Dante gives very minute, although somewhat obscure, accounts of the essence and invention of stanzaic form (*cobla* in Provençal), in which the Romance poetries excelled from the first. The stanza was a group of lines formed on a regular and recurrent arrangement of rhymes. It was natural that the poets of Provence should carry to an extreme the invention of stanzaic forms, for their language was extravagantly rich in rhymes. They invented complicated poetic structures of stanza within stanza, and the *canzo* as written by the great troubadours is a marvel of ingenuity such as could scarcely be repeated in any other language. The extreme fulness and elaboration of the Provençal poets, however, has been serviceable as placing a very high ideal of structural skill before the poets of all succeeding times, and it was of immense value in directing the experiments of the earliest poet-artists of Italy and France.

In French poetry, successive masters corrected the national versification and drew closer round it the network of rules and principles. The alexandrine was invented in the 12th century, as a counterpart to the hexameter of the ancients, by Alexander de Bernay. A great part is played in French metre by masculine and feminine verse: the former is a verse which closes with a letter which is not *e mute*; the latter a verse which closes with *e mute*, or with *e mute* followed by *s*, or by the consonants *nt*. Masculine rhyme is that which combines two masculine verses, and feminine that which unites two feminine verses; and in regular verse such couplets must be alternated. Elision is the rule by which, in the scansion of a verse, the letter *e* at the end of a word is suppressed when it immediately precedes *e mute* or a non-aspirated *h*. These and other immutable rules were laid down by Malherbe, and by Boileau in his *Art Poëtique* (1674), and for more than a century they were implicitly followed by all writers of verse. It was the genius of Victor Hugo which first enfranchised the prosody of France, not by rebelling against the rules, but by widening their scope in all directions, and by asserting that, in spite of its limitations, French verse was a living thing. The richness of Hugo's rhymes is proverbial, and the boldness and flow of his alexandrines exceeded everything which had been so much as dreamed of before his time. The revolution he brought about proved universal, and disciples like Théophile Gautier could say, in the face of the critics and grammarians of the classic school, "If we suspected that Victor Hugo had written a single bad verse, we should not dare to admit it to ourselves, in a cellar, without a candle." Boileau and Hugo, therefore, have been the two lawgivers of the French Parnassus. The rules of French verse being, in fact, very severe, and weakness, excess of audacity and negligences of all sorts being very harshly repressed, it is not surprising that, as the personal authority of Hugo declined, various projects were started for lightening the burden of prosodical discipline. Since 1880 those projects have been numerous, and a great many poets of genuine inspiration have written in different forms of what is called "free verse."

Teutonic.—In very early times the inhabitants of the Germanic countries developed a prosodical system which owed nothing whatever to classical sources. The finest examples of this Teutonic verse are found in Icelandic and in Anglo-Saxon. The line consisted of two sections, each containing two strongly stressed syllables, and of these four long syllables three were alliterated. It is plain that there can be detected in ancient Teutonic verse but three severe and consistent rules, viz. that the section, the strong accentuation, and above all the alliteration must be preserved. We find this to be the case in High and Low German, Icelandic, Anglo-Saxon, and in the revived alliterative English poetry of the 14th century, such as "Piers Plowman." There are differences, however, which depend on such facts as that the Icelandic poems are mainly lyrical and the Anglo-Saxon epics are narrative. As time went on, under the pressure of south European practice, alliteration ceased to be regarded as the sole and sufficient ornament of Teutonic verse, and rhyme was occasionally used, but this was a concession which proved fatal to the type. With this use of rhyme, the High German poetry begins to cease, while England becomes the centre of

[1] But see the article PROVENÇAL LITERATURE.

Teutonic metrical composition. In Icelandic poetry there was a highly artificial verse-system known as court-verse (*dróttkvaett*), which consisted of alliterative groups of two lines each, arranged in staves of eight lines. When we consider primitive Teutonic verse closely, we see that it did not begin with any conscious art, but, as Vigfussen has said, "was simply excited and emphatic prose" uttered with the repetition of catchwords and letters. The use of these was presently regulated. Alliteration of stressed root-syllables formed the basis of Teutonic verse, as quantity had formed the basis of Greek verse. A study of the "Heliand" and the "Lay of Hildebrand" in Old German, of the "Atli" and "Harbard" lays in Icelandic, and of the writings attributed to Beowulf, Cædmon and Cynewulf in Anglo-Saxon, will show the general unity and the local divergences of this class of verse.

English Metre.—The first writer in whom there has been discovered a distinct rebellion against the methods of Anglo-Saxon versification is St Godric, who died in 1170. Only three brief fragments of his poetry have been preserved, but there is no doubt that they show, for the first time, a regular composition in feet. A quotation will show the value of St Godric's invention:—

"Saintë | Nicholaes, | Godes | druth,
Tymbre us | fairë | sconë | hus,
At thy | burth, | at thy | bare,
Saintë | Nicholaes, | bring uswel thare."

From this difficult stanza down to the metres of modern English the transition seems gradual and direct, while the tradition of Anglo-Saxon alliterative prosody is abruptly broken. The fragments of St Godric appear to be independent of one another, and therefore indicate that the division of lines into feet is not accidental. They are much less dubious, and more firm as the basis of an hypothesis, than the famous quatrain[1] about the singing of the monks of Ely, which is perhaps a little earlier in date than the fragments of St Godric. This has much picturesque beauty, but if it is carefully examined the actual scheme of it as metre seems to evade detection. The Ely singer warbled, not knowing what he sang, but St Godric knew perfectly well, and must have been a deliberate innovator. There is still more definition of feet in the *Poema Morale*, printed by Dr Morris, which is supposed to date from about 1200. In longer pieces, and particularly in the *Ormulum*, and in the *Brut* of Layamon, which belong to the early part of the 13th century, we find, on the whole, less definite abandonment of the Anglo-Saxon system of prosody, but nevertheless a prominence given both to rhyme and to rhythm. In Layamon, particularly, the recognition of a recurrent verse of four accents is unquestionable. The place of this poet in the history of prosody is very carefully noted by Guest, who remarks that in Anglo-Saxon verse, the syllables which take the alliteration are always accented, while in the later metres, where alliteration was combined with rhyme, the former is often thrown upon an unaccented syllable. "Layamon appears to take a middle course. It would seem he gave accents both to his rhyming and his alliterative syllables; but the former were often obliged to content themselves with a false accent." An advance was made about fifty years later in *Genesis and Exodus*, a poem published by Professor Skeat, which has such great value in the proof it gives of the extension of verbal melody, that Saintsbury has said that "it contains more of the kernel of English prosody, properly so called, than any [other] single poem before Spenser." The phenomenon which we meet with in all these earliest attempts at purely English verse is the unconscious determination of writers, who had no views about prosody, to follow their national instinct in the direction of grouped feet and rhymes. This is further emphasized in *Horn* and *Havelok*, and in the smoother octosyllabics of the 14th-century metrical romances, where the rhymes become very frequent, with an occasional short line or *bob*, to prevent monotony of effect. Few of these romances have much literary value, but their prosodical value is very great, for we see in them the normal movement of English verse becoming fixed to certain principles beyond any possibility of escape:—

"So fair | he spak- | ë him withal,
He light- | ed down- | ë, in | the hall,
Boundë | his mare | among | them all,
And to | the board- | ë won."

This, from *Sir Percevale*, is, it must be allowed, an unusually correct example; the uncouth 14th-century writers did not commonly arrive at their effect without much more irregularity and wavering than this, but the design is evident even in their worst examples. Between 1210 and 1340 not a single English poem of importance is known to have been written in the old alliterative measure of the Anglo-Saxons. But at the latter date there set in a singular reaction in favour of alliteration, a movement which culminated, after producing some beautiful romances, in the satires of Langland. Those writers, and they were many, who preserved foot-scansion and rhyme, during this alliterative reaction, became ever closer students of contemporary French verse, and in the favourite octosyllabic metre "the uncompromising adoption of the French, or syllabically uniform, system is the first thing noticeable" (Saintsbury). This tendency of Middle English metre culminates in the work of John Gower, which is singularly polished in its rhyming octosyllabics, although unquestionably nerveless still, and inelastic.

It is, however, to Chaucer that we turn for far greater contributions to English verse. He it was who first, with full consciousness of power as an artist, adopted the use of elaborate stanzas, always in following of the French; he it was who first gained freedom of sound by a variation of pause, and by an alternation of trochaic and iambic movement. It is the lack of these arts which keeps Gower and his predecessors so stiff. In particular Chaucer, in his first period, invented rime-royal, a stanzaic form (in seven decasyllabic lines, rhymed *a b a b b c c*), peculiarly English in character, which was dominant in our literature for more than two hundred years; it was used in the long romance of *Troilus and Creseide*, where English metre for the first time displays its beauty to the full. The importance of rime-royal is displayed in the fact that its sixth and seventh lines actually form the decasyllabic couplet, which is commonly held to be a later discovery of Chaucer's, in *The Legend of Good Women*. This is the heroic verse, in which *The Canterbury Tales* are mainly composed, and this metre of five accents, with couplet-rhyme, became so powerful in the future history of English poetry that it may almost be taken as the central and most characteristic of our verse-forms, as the alexandrine couplet is in French and Dutch prosody. It seems to have been originally called riding-rhyme, the name by which Gascoigne describes it (1575).

It is impossible here to do more than indicate very briefly those fluctuations which English prosody underwent when the learned and vivid example of Chaucer was withdrawn. The metres of Lydgate and his successors were discordant and feeble; their ears had learned but very incorrectly the lesson of the master. Lydgate, in particular, went back to an earlier type, and showed himself more skilful in the old eight-syllable measure than in the new decasyllable. More interesting to the prosodical student than the work of these or later Chaucerians is the influence exercised throughout the 15th and early 16th centuries by the popular ballads, of which "Chevy Chase" is believed to be the oldest surviving example, while "The Tale of Gamelyn" is the longest. The introduction of the loose, elastic ballad-quatrain, with its melodious tendency to refrain, was a matter of great importance in the metamorphosis of British verse. The degenerate forms employed by the English 15th-century poets in attempting more regular prosody were in some measure connected by the greater exactitude of the Scotch writers, particularly of Dunbar, who was by far the most accomplished metrist between Chaucer and Spenser.

[1] Merie sungen ðe muneches binnen Ely,
ða Cnut ch[in]ing reu ðer by;
"Roweð, cni[h]tes, noer the land
and here we þes muneches sæng."

But Wyatt (1503–1542) was long considered the father of modern English verse, and though we now plainly enough perceive that before his day all the essential discoveries and inventions had been made, he nevertheless deserves great honour as a pioneer. He introduced, from France and Italy, the prosodical principles of the Renaissance—order and coherency, concentration and definition of sound—and that although his own powers in metre were far from being highly developed. He and his more gifted disciple Surrey introduced into English verse the sonnet (not of the pure Italian type, but as a quatorzain with a final couplet) as well as other short lyric forms. To Surrey, moreover, we owe the introduction from Italian of blank verse, the rhymeless metre of five accents, which has taken so prominent a place in subsequent English poetry.

With the heroic couplet, with blank verse, and with a variety of short lyric stanzaic measures, the equipment of British verse might now be said to be complete. For the moment, however, towards the middle of the 16th century, all these excellent metres seemed to be abandoned in favour of an awkward couplet of fourteen feet, which may have had some relation with the French alexandrine. It was always, as Saintsbury says, "a very uncertain and risky metre, settling down with a dangerous acquiescence into doggerel and sing-song." It was to break up this nerveless measure that the remarkable reforms of the close of the century were made, and the discoveries of Wyatt and Surrey were brought, long after their deaths, into general practice. In drama, the doggerel of an earlier age retired before a blank verse, which was at first entirely pedestrian and mechanical, but struck out variety and music in the hands of Marlowe and Shakespeare. But the central magician was Spenser, in whom there arose a master of pure verse whose range and skill were greater than those of any previous writer of English, and before whom Chaucer himself must withdraw. It is not too much to say that Spenser took all the elements of English verse, as they had existed in more or less timid and undeveloped shape for four centuries, and that he moulded them together into an instrument capable, for the first time, of expressing, or accompanying, every passion, every emotion, every variety of sentiment or instinct, which stirs the human breast. His great work was that of solidification and emancipation, but he also created a noble form which bears his name, that Spenserian stanza of nine lines closing with an alexandrine, which lends itself in the hands of great poets, and great poets only, to magnificent narrative effects.

It was at this moment that a final attempt was made to disestablish the whole scheme of English metre, and to substitute for it unrhymed classic measures. In the year 1579 this heresy was powerful at Cambridge, and a vigorous attempt was made to include Spenser himself among its votaries. It failed, and with this failure it may be said that all the essential questions connected with English poetry were settled.

There is enough to fill a score of volumes in the mode in which the poets from Spenser downwards have employed the laws of English verse, but he was the latest of the legislators who laid down the framework of those laws. It is not possible in this place to enter into such themes as the rise and fall of Elizabethan dramatic blank verse; the perfection of the song and the development of the sonnet; the extraordinary virtuosity of Milton; the contest between enjambement (which permits the extension of the sentence beyond the limits of the distich) and the couplet as introduced by Waller; the victory of that couplet, and its use from 1670 to 1800; the slow growth of ode, which had been one of Spenser's inventions; the revivals of prosodical taste in the 19th century; the extraordinary advance in freedom of anapaestic movement.

It may generally be remarked in connexion with the very various, copious and often chaotic criticism of English verse, that it has been a misfortune, from the earliest times, that pedantic and chimerical theories have too often invaded the study of metre. They had tended, from the times of the Alexandrian grammarians down to our own, to treat as a dead thing that vivid and elastic art of poetry whose very essence is its life. In modern times not a few theorists have allowed themselves to diverge into the most extraordinary chains of musical and even of mathematical conjecture and have been easily led, in the practice of their ingenious learning, to forget that what they are talking about is the vehicle in which tremulous and ardent thoughts are conveyed to the hearts of men. The poet knows the law by instinct, but he treats it as a living guide; he varies the pause, he manipulates the accent, he gives the vital element of freedom to the verse which he has founded upon discipline. It is extremely doubtful whether any youthful poet was even helped by prosodical instruction; his earliest measures are imitative; he does not compose consciously in "tribrachs" and "iambs"; he would gape in astonishment if asked to define the "pyrrhichian hypothesis"; his bursts of enthusiasm are not modified by a theory of "trisyllabic equivalence." The old formula of verse, "variety in unity," holds good in all languages, countries and times; the delicate rapture involved in a brilliant combination of rhyme and metre is a matter which is regulated, indeed, on a consideration of the laws of prosody, but depends on other and wider qualities of a moral and an aesthetic order.

VERSECZ (Ger. *Werschetz*), a town of Hungary, in the county of Temes, 235 m. S.S.E. of Budapest by rail. Pop. (1900) 25,199. It has a handsome parish church and is the seat of a Greek Orthodox bishop. Versecz is one of the principal wine-producing centres in Hungary, and the red wines and brandy produced here enjoy a great reputation. Near the town are remains of a Roman castle, and a Roman rampart and trench which extend for about 60 m. to the north. During the revolutionary period of 1848–49 the Hungarians defeated the Servians here on the 11th of July 1848, while on the 19th of January 1849 the town was occupied by the Austrian troops.

VERTEBRATA, a large branch of the animal kingdom, of which the characteristic members are mammals, birds, reptiles, batrachians, fish and cyclostomes, the craniate vertebrates of modern zoology. These include all the animals which possess "vertebrae," pieces of bone or cartilage jointed to form a "backbone" or spinal column (see Spinal Cord), although in some of the lower members of the group the segmentation of the spinal column is imperfect. That such animals formed a natural group was understood from the earliest times. Aristotle placed them together as "Enaima;" or sanguineous animals, distinguishing them from the "Anaima," which he believed to be bloodless. Later it was discovered that the so-called bloodless animals contained uncoloured blood, and the vertebrates were distinguished as red-blooded, until G. L. C. F. D. Cuvier showed the existence of red blood in some other animals. C. Linnaeus made Mammalia, Aves, Amphibia and Pisces the first four classes of the animal kingdom, but suggested no corporate name for them. In 1788 A. J. G. K. Batsch united them into a great division, for which he proposed the name "Knochenthiere," bony animals. J. B. P. Lamarck carried the idea further, and first clearly recognized the importance of the vertebral column in classification; to him is due the division of the animal kingdom into Vertebrata, which included all the craniate vertebrates, and Invertebrata, which included all other animals. These names and the dichotomy they imply have persisted from their convenience, although zoological science has come to recognize that the groups are not morphologically equivalent and that the division is not logical. Cuvier showed that there were four groups in the animal kingdom, each corresponding to a definite type or plan of structure, and that craniate vertebrates composed only one of these groups, invertebrates including three. In the progress of zoology it has become clear that the coelomate animals fall into a very large number of distinct groups or types, and that the vertebrates are only one class amongst many morphologically distinct classes. It has been shown further that amongst the animals that Lamarck would have placed in the Invertebrata there are several which, although devoid of vertebrae or cranium, must be associated with vertebrates in any natural system. Closer investigation of the anatomy and embryology of the craniate vertebrates showed that the possession of a jointed vertebral column was not a fundamental characteristic of the group. In some creatures, such as sturgeons and lampreys, the position of the jointed vertebral column is occupied by an unjointed rod, the so-called notochord, whilst all the Vertebrata pass through an embryonic stage in which a similar elastic unjointed notochord exists as the precursor of the jointed column. It was further found that all the vertebrates of Lamarck displayed either in the embryonic condition alone, or both in embryonic and adult conditions, a set of passages leading from the anterior-lateral portion of the body into the cavity of the pharynx, and known as gill-slits, because in those creatures in which they become functional for aquatic respiration they lodge the gills or branchial tufts. Further, it was found that in all vertebrates the great central mass of the nervous system, known as the brain and spinal cord, is in reality a hollow tube with more or less thickened walls, developed as a strand of tissue along the dorsal surface of the embryo, which sinks downwards and inwards to form a hollow tube lying dorsal to the notochord.

In 1866 A. Kowalewsky, in a memoir that is one of the classics of vertebrate morphology, worked out the development of *Amphioxus*, then recognized as the simplest of the vertebrate group, and compared it with the development of an Ascidian, one of a group then termed Tunicate Mollusca, and showed that the latter creature, in its larval stage, possessed, like *Amphioxus*, a notochord, gill-slits and a hollow dorsally placed nerve-tube. In 1877 E. Ray Lankester published a classification of the animal kingdom in which he definitely associated all the Tunicates with the vertebrates, and subdivided Vertebrata as follows: Branch A., Urochorda, which contained the Tunicates and was characterized by the limitation of the notochord to the caudal region; Branch B., Cephalochorda, containing *Amphioxus*, in which the notochord extended from the extreme tip of the tail to that of the snout; Branch C., Craniata, containing the Cyclostomes, Pisces, Batrachia, Reptilia, Aves and Mammalia, in which the anterior extremity of the notochord ended in the base of a cranium. Later, F. M. Balfour adopted the system of Lankester, but proposed to replace the term Vertebrata, which was anatomically misleading, by the new term Chordata, as the latter term laid stress on the existence of the notochord as the fundamental character of the group. A. Kowalewsky had shown as early as 1866 that the marine worm *Balanoglossus*, described by Della Chiaje at the end of the 18th century, possessed a set of gill-slits similar to those of *Amphioxus* and Tunicates. From 1884 to 1886 W. Bateson published a series of studies in which he suggested that there was present in *Balanoglossus* a representative of the notochord, and that a portion at least of its nervous system was a hollow, dorsally placed tube. On these grounds, coupled with the presence of gill-slits, he proposed to add yet a lower branch to the Chordata, to include *Balanoglossus* and to be termed Hemichorda, but neither Bateson nor zoologists who have written since have accepted the vertebrate affinities of *Balanoglossus* with complete confidence. Still more diffidently, S. F. Harmer and others have suggested that *Cephalodiscus* and *Phoronis*, still more lowly marine invertebrates, have claims to be associated with the Chordata.

It may be accepted definitely that *Amphioxus* and the Tunicates must be associated with the craniate vertebrates of Lamarck. With regard to the terms Vertebrata and Chordata, usage still differs. Those who wish to make the names of the larger groups significant labels prefer the term Chordata, and on the whole seem to be prevailing, but there remain many zoologists who prefer the designation with historical associations, and regard it as immaterial if, in the advance of knowledge, the connotation may have been so changed that the term has become conventional rather than verbally significant.

The characters and affinities of the lower groups that have been included under Chordata are discussed in the articles HEMICHORDA, BALANOGLOSSUS, PHORONIDEA, PTEROBRANCHIA, TUNICATA and AMPHIOXUS, so that it is necessary here to deal only with the general characters of the Chordata or Vertebrata Craniata, and to consider the views that have been advanced with regard to the origin of vertebrates.

The Vertebrata Craniata share with the Cephalochordata the fundamental characters of the group Chordata. They are bilaterally symmetrical animals with a well-marked metameric segmentation of the muscles and muscle septa, with a gut opening by an anterior ventral mouth, with lateral gill-slits in the embryo or adult, and with a ventro-posterior anus; with a dorsal tubular central nervous system, under which lies in the embryo or adult an unsegmented notochord of endodermal origin; with the body prolonged posteriorly to the anus to form a metamerically segmented tail containing notochord, nervous system and muscles; with a spacious coelomic cavity and separate blood-vascular system. They differ from the Cephalochordata in the extreme cephalization of the anterior segments of the body, including the formation of an enlarged brain with paired sense organs, the nose, eyes and auditory apparatus, and the formation of a cranium, and in the structure of the skeleton, heart, liver and organs of excretion and reproduction.

Evidence points to the origin of the Cephalochordata and the Craniata from a common ancestor in which metameric segmentation of the mesoblast and the nervous system was complete and regular. This condition has been retained by *Amphioxus*, but in the Craniata has been much modified. The lateral mesoblastic plates with their contained coelom are unsegmented in craniates, although traces of the primitive segmentation are visible in the development of Cyclostomes. The dorsal mesoblastic somites with the segmental musculature derived from them retain the segmental condition in *Amphioxus* and in the trunk region of craniates, but in the head region of the latter there has taken place a fusion or cephalization more pronounced in the higher forms, where the head is distinct from the trunk, than in lower forms where the head passes gradually into the trunk. The exact number of somites which have been cephalized is difficult to estimate, and certainly varies in different cases, but it appears to be certain that three, immediately anterior to the otic region, have been transformed into the optic muscles. Those behind the otic region (metaotic somites) vary from nine to eleven, and in Cyclostomes give rise to segmental muscles in series with those of the trunk. In true fish and higher Craniates the anterior one or two of these metaotic somites practically disappear, whilst of the remainder none form complete segmental muscles, but various portions of them give rise to muscles associated with the branchial apparatus (epibranchial and hypobranchial), the dorsal portions fading away. In other words, the metameric series continued from the trunk to the anterior end of the body in the ancestral form, retained by the Cephalochorda, and of which traces remain in the development of the Craniata, has been modified in the adult Craniata by the suppression of certain portions and the specialization of other portions to form an unsegmented structure. The process of cephalization, with, however, less complete destruction of the segmental arrangement, has also affected the anterior nerves of Craniata and brought about the distinction between cranial and spinal nerves which is a feature of the Craniates. The ancestral form must be supposed to have given off from its central nervous system lateral nerves segmentally arranged in pairs. Each member of each pair possessed two roots, a dorsal and a ventral root, possibly remaining separate, as in the Cephalochordata and the cranial nerves of Craniata, possibly joining to form a common trunk, as in the spinal nerves of Craniata. The ventral roots consisted of motor fibres passing straight outwards to innervate the segmental muscles derived from the dorsal somites; the dorsal roots took a longer course, arching outwards and round the body to supply the visceral muscles, the mucous membranes, the skin and the sense organs connected with these. It appears, moreover, that the ventral roots remained in strict association with the muscular somites to which they corresponded, and wandered beyond their own segmental areas only with these muscles, whereas the ramifications of the dorsal fibres had a wider range and were less closely bound to segmental regions. Such a primitive condition has been retained by *Amphioxus*, but in the case of Craniata only by the spinal nerves. Almost every great anatomist has contributed to working out the history of the cranial nerves, and it would be a hopeless task to make a just allocation of credit for the various steps which have led to our present knowledge, but the names of C. Gegenbaur, F. M. Balfour, A. M. Marshall, J. W. van Wijhe, N. K. Koltzoff, Miss J. B. Platt, J. Beard, H. V. Neal and E. S. Goodrich are conspicuous. The Craniates are characterized by the presence of ten pairs of cranial nerves, numbered usually I. to X., from before backwards, with a course and distribution fundamentally identical throughout the group from the lowest fish to man, whilst in the higher forms an additional eleventh and twelfth pair have been assumed from the trunk or neck. Pairs I. and II. are the nerves of special sense of smell and sight, and in all probability are morphologically distinct from true segmental pairs. Pairs III. to X. represent various portions of primitive segmental pairs, modified in association with the cephalization of the anterior region of the body. III., IV. and VI. innervate the muscles of the eyeball, and represent the ventral roots of the three prootic somites; the dorsal root of the anterior of these three passes to the anterior portion of the head as the so-called *nervus ophthalmicus profundus*. The V. of human anatomy, the *trigeminal*, is formed almost entirely from the dorsal root of the nerve of the second prootic somite, whilst the VII. or *facialis* of human anatomy similarly represents the greater part of the dorsal root of the third prootic somite, whilst the remaining and lesser portion of that root forms the VIII. or *auditory* nerve of human anatomy. The IX. or *glossopharyngeal* represents the dorsal root of the first metaotic somite, the ventral root of which persists in Cyclostomes but disappears together with the somite in higher Craniates. The X. or *vagus* of human anatomy represents the dorsal root of the second metaotic somite. The backward extension of the vagus to supply the regions corresponding to the posterior gill-slits and internal viscera has been interpreted variously. The explanation at first sight most probable, and that has been advocated by Gegenbaur and many other anatomists, is that the dorsal roots corresponding to a number of somites have fused to form a single system. The ventral roots of the somites in question have a varying fate, being fully represented in the Cyclostomes by nerves to musculature developed from these somites, whilst in the higher forms thay have in great part disappeared. Evidence seems to point to a similar disappearance of the dorsal roots of the branchial somites posterior to the first supplied by the vagus; but as remnants of them have been traced in the development of the various Craniates, it seems as if the vagus were not in reality a compound nerve, but the extension of the nerve arising from a single dorsal segmental root. Notwithstanding some dubiety in detail, the main proposition remains clear: the cranial nerves of Craniates have arisen, in the course of a process of cephalization, from a primitive set of segmental nerves in series with those of the trunk, by a suppression of certain portions and an expansion and specialization of other portions. The work of a large number of anatomists has shown that the fundamental morphological characters of the cranium and brain, organs in which the Craniates are most clearly marked off from Cephalochordates, are fundamentally alike throughout the group. The original crude theory of L. Oken and the poet Goethe, that the skull was composed of expanded and fused vertebrae, was disproved by T. H. Huxley and Gegenbaur. There can be little doubt, however, that the region behind the infundibulum, consisting of part of the optic capsules, the anterior extremity of the notochord, the parachordals (for details as to these see article SKELETON) and the corresponding lateral and dorsal elements with their suspended visceral arches represent at least three cephalic somites, and that the process of cephalization has played an important part in the formation of the cranium as it has in the case of the nerves and muscles of the head. The region of the cranium anterior to this is probably a forward growth of the primitive head, produced in association with the development of the organs of smell and sight, and thus is different in kind from the posterior region. But as *Amphioxus* is obviously degenerate in the region of the head, no source of information exists as to the exact mode in which the development of the head of the ancestral vertebrate took place.

It is still less possible to lay down anything definite as to how far the structure of the brain of Craniates conforms with a theory of origin by a process of cephalization of metameric segments. The minute expansion at the anterior end of the nerve tube of *Amphioxus* cannot be called a brain, whilst the brain of all the Craniates is identical in morphological type and so complex that it must have behind it a long history of development. The embryonic Craniate brain appears as three dilatations of the neural tube, respectively the posterior or hind-brain, continuous with the spinal cord, the mid-brain and the fore-brain. From the hind-brain there arises the medulla oblongata or myelencephalon behind, and the metencephalon in front, the dorsal wall of which gives rise to the cerebellum. The hind-brain is closely similar in structure to the spinal cord, and gives rise to all the segmental cranial nerves except the *patheticus* and *motor oculi*. The sides of the mid-brain thicken and give rise to the optic lobes; its floor forms the crura cerebri, whilst the *oculomotor* and *patheticus* nerves take origin from it. The fore-brain divides into a posterior thalamencephalon and an anterior telencephalon. Thickenings of the floor of the thalamencephalon give rise to the optic thalami; the paired optic lobes grow out from its sides; the pineal body, which primitively was a pair of dorsal eyes, grows from the roof and the infundibulum from the floor. The telencephalon in front grows out secondarily to an extent progressively increasing in the higher groups and forms the corpora striata, the cerebral lobes and the rhinencephalon. The most plausible interpretation is that the mid- and hind-brains represent a cephalized continuation of the spinal cord, probably originally metamerically segmented, whilst the fore brain has been developed primitively in association with the organs of smell and hearing, and secondarily in connexion with the increasing elaboration of the higher functions of the brain and the development of the association centres of which the cerebrum is the seat.

The details of the structure and development of the sense-organs, gill-slits and visceral organs of Craniates are sufficiently discussed in the articles dealing with the separate classes of the group. It is necessary to refer, however, to new light thrown on the structure and morphology of the renal excretory organs due chiefly to the investigations of Goodrich. The excretory organs of the vast majority of invertebrate coelomate animals are essentially what are known as nephridia. Nephridia in their simplest form are excretory tubules growing from the exterior inwards, and removing from the surrounding tissues or blood vessels waste matter which they discharge to the exterior. In many cases these tubules acquire secondary openings to the coelom, termed nephrostomes and serving to remove waste matter from that space. Finally, in metamerically segmented invertebrates the nephridia frequently appear in segmentally disposed pairs. Gegenbaur, C. Semper, B. Hatschek, and many other anatomists have compared the kidneys of Craniates with nephridia, supposing the segmental tubules with their coelomic apertures to represent nephridia, which, instead of discharging directly to the exterior by pores in the segments in which they are situated, have come to discharge at each side into a longitudinal common duct with a posterior aperture. The excretory system of *Amphioxus* undoubtedly consists of true nephridia, morphologically identical with those of the invertebrate coelomates. The latter, however, may also possess a different set of organs, also frequently appearing as segmentally arranged tubules. These are the genital funnels which develop outwards from the coelom, and serve for the discharge of the genital products. It is with the latter that the segmental tubules of the Craniata are to be compared, and the possession of a different type of excretory organ is one of the most vital distinctions between the Craniata and the Cephalochordata.

Origin of the Vertebrata.—The recorded fossil history carries us backwards with comparative ease from the highest mammals to the lowest members of the Craniates. Remains of the latter, abundant in the palaeozoic rocks, were undoubtedly true Craniates, allied with the Cyclostomes and the lower fishes, but showing no more than superficial and dubious resemblances to the members of any other group. We have to rely upon general inferences which lead to much ingenious argument and little certain result. The Craniates can be traced back to fishes not unlike the modern shark or dogfish with little dubiety. The Cyclostomes, although true Craniates, present an obviously simpler type of structure: the head is less cephalized and therefore less distinct from the trunk; lower jaw, true teeth and dermal armature are absent, whilst there are other simplifications in the structural type. Very general assent could be obtained for the proposition that one stage in the ancestry of the Vertebrates must have been not unlike a simplified Cyclostome, a bilaterally symmetrical coelomic animal, elongated and fish-like in shape, but without paired limbs, with a smooth, soft skin, a ventral mouth without teeth or lower jaw and probably surrounded by labial palps, with lateral gill-slits and a ventro-posterior anus; with an unsegmented notochord and a dorsal tubular nerve cord. The brain, however, must have been expanded, and there must have been paired organs of smell, two lateral eyes and probably two dorsal eyes, and a large paired auditory apparatus. The mesoblastic system of muscles and fibrous skeleton was highly and regularly segmented, but in the anterior region cephalization had proceeded to a considerable extent. The resemblances between such a creature and *Amphioxus* are so close that they cannot be dismissed. *Amphioxus* no doubt is specialized in many respects, and probably degenerate in others, just as, if we go to the other pole of the Craniates, we know that although the Anthropoid Apes are the nearest living representatives of the ancestor of man, they are specialized in many respects and almost certainly degenerate in other respects. If we carry those processes of progressive change by which the Cyclostome type has passed into the low fish type, and the low fish type into the higher Craniate type, backwards towards *Amphioxus* we reach the conception of an ancestral creature essentially a Cephalochordate, differing no doubt from *Amphioxus* in various details, as one member of a group differs from another, but specially marked by the possession of better developed cranial sense organs and by the presence of a coelomostomic instead of a nephridial excretory system. Paired sense organs of an elaborate character have arisen in many groups, and there seems to be no special difficulty in supposing that those characteristic of Craniates have arisen independently in that group, *Amphioxus*, although in that respect partly degenerate, being degenerate from a stage in which the cephalic sense organs were extremely simple. The different type of excretory system presents even less theoretical difficulty, as both types of segmental funnel exist amongst Invertebrates and may even be present in the same animal. If we follow the process of progressive change still further back, we reach a stage in which cephalization had practically disappeared, and where even metameric segmentation was in a much less advanced condition. The tadpoles of Ascidians, and still more remotely *Balanoglossus*, although still less than *Amphioxus* to be regarded as actual ancestral vertebrate types, give images of some of the many phases in which the ancestral type may have been exhibited. It is needless to say that the creatures exhibiting such a stage in the ancestry of the Vertebrates would have formed simply one in the vast series of marine coelomate types which the anatomy of the Invertebrates shows us to have existed. Its distinguishing features would have been the presence of gill-slits, of the skeletal rod, known as the notochord, and of the dorsal tubular nervous system. We cannot make even profitable guesses as to the exact conditions under which these features, or the corresponding features of other coelomate types, arose in the kaleidoscopic differentiation of form, but consideration of the general morphology of the nervous system enables us to see the Chordate ancestor in its true perspective amongst other coelomic groups. In the Coelentera the nervous system appears as a diffused layer of cells and fibres, underlying, and in close connexion with, the epidermis. This diffused layer may thicken in special regions, forming rings round apertures, radial bands, and so forth, whilst in the intervening areas it disappears. In the different groups of Coelomates specialized bands and strands have formed in this way from a primitive diffuse system, giving rise to the nervous patterns distinctive of the various groups, whilst a second process, that of inward migration from the epidermis, produces further changes. In the Turbellaria there have been formed two ventro-lateral cords with variously placed anastamoses; in the Trematodes, two ventral, two lateral and two dorsal cords with variously placed anastomoses, and in the Cestodes two lateral and in some cases one dorsal cord. In the Nemertea the primitive continuous sub-epidermal sheath is retained with two lateral and sometimes one dorsal thickening. In the Nematodes there are one dorsal, one ventral and at each side two lateral thickenings, sometimes separated cords, sometimes mere sub-epidermal bands, whilst the traces of a circum-oesophageal ring may be regarded as another specialization of the primitive complete sheath. In *Balanoglossus* there is a continuous sheath with a dorsal and ventral band, the latter in certain regions showing traces of a tubular structure. In Annelids and Arthropods there are two ventral bands tending to unite in the median ventral line, and a circum-oesophageal collar. In the Chordates there is a continuous dorsal band, which secondarily migrates inwards and becomes tubular. In almost any of these types, as the individual becomes more integrated, there is a tendency for the nervous matter of the specialized areas to become still further massed; and in bilaterally symmetrical animals with forward progression and the beginning of cephalization a specially important mass forms something comparable with a brain in special relation with the sense organs of the primitive head. If the problem of vertebrate origin be considered from the wide point of view of comparative anatomy, it becomes no more difficult nor remarkable than the differentiation of any other type amongst simple, marine, unsegmented, or little segmented, wormlike creatures. It is obvious, however, that such a theory of origin cannot expect confirmation from the geological record, as it supposes a differentiation of the main chordate characters in a stage too simple to leave fossil remains.

Reference must be made, however, to definite theories of the origin of Vertebrates which have been successively urged by anatomists. A. Dohrn, if not the inventor, was the most ingenious advocate of the Annelid theory. He recognized the fundamental importance of segmentation in vertebrate structure and sought for a highly segmented ancestor. Partly influenced by Ray Lankester's studies on degeneration, he held that the apparently simplest living members of a group may give misleading clues with respect to the ancestral line, and he devoted much brilliant anatomical and embryological work to develop the thesis that *Amphioxus* and the Tunicates were degenerate offshoots from a higher vertebrate stock. He took a Chaetopod worm as the closest living representative of the stock of all segmented animals, and in particular of the Vertebrates, laying stress on the segmentation, the large coelom, the segmental excretory tubules, the vascular system with red blood, the segmentally disposed branchiae, the lateral organs of locomotion, and the tendency to form a distinct head. The chief difficulty was the nervous system, and this he explained by accepting an idea propounded many years before by De Blainville, that the dorsal surface of Vertebrates was homologous with the ventral surface of Annelids and Arthropods. He assumed that the ancestral type was a marine creature in which reversal of surface was of little physiological moment. He supposed that a new mouth had been formed, probably by a coalescence of a pair of gill-slits on what was to be the ventral surface of the vertebrate, and that the old invertebrate mouth with the downward turn of the anterior end of the alimentary canal, between the diverging ends of the ventral nerve cords, was to be sought for in the roof of the vertebrate brain, possibly the pineal body. Dohrn's theory has failed to find acceptance for many reasons, of which the chief are the difficulty as to reversal of surfaces, the knowledge that segmentation occurs independently in many groups of animals and in different organs, greater knowledge of the vascular, excretory and nervous systems, and in particular the discovery that the pineal body was a degenerate eye. F. M. Balfour from the first refused to accept Dohrn's theory and suggested that the dorsal position of the nerve cord in Vertebrates could be accounted for by supposing that the primitive condition was a lateral cord at each side such as were then known to occur in Nemertines, and that these cords had fused dorsally in Vertebrates, ventrally in Annelids. A. A. W. Hubrecht soon afterwards discovered the existence of a continuous nerve sheath in Nemertines, and he and Ray Lankester suggested a Nemertine origin for Vertebrates, and homologized the notochord with the proboscis sheath, Ray Lankester, in particular, pointing out that the tubular condition of the vertebrate nervous system was secondary, that it consisted essentially of a dorsal band, which sank inwards, and that the canal might have been at first an epidermal water canal. These authors were emphatic in laying stress on the view that no actual Nemertine could be supposed to represent the vertebrate ancestor, but that the Nemertines were to be taken merely as showing the kind of material out of which the vertebrate structure, and in particular the vertebrate nervous system, might have arisen. The view adopted in this article as given above, is in reality an extension of the Hubrecht-Lankester theory.

The theory of vertebrate origin that has been most elaborately expounded is W. H. Gaskell's hypothesis that they are descended from Arthropods. Gaskell accepts Dohrn's view of the importance of segmentation and of the degeneracy of *Amphioxus* and Tunicates, but rejects the conception of a reversal of surfaces. He takes the larval stage of a Cyclostome as the most generalized living representative of the essential vertebrate type, and selects *Limulus*, the kingcrab, in a very general way, as the closest living representative of such an Arthropod type as might have been the vertebrate ancestor. The starting-point of Gaskell's theory is the conception of the vertebrate nervous system as a band of nervous tissue which immediately underlies and gradually grows up round a distinct epidermal tube, the tube which forms the vesicles of the brain and the central canal of the spinal cord. Ray Lankester had already applied this to the Nemertine theory, but Gaskell urges that it affords an immediate comparison with Arthropod structures. The ventral mouth of *Limulus* leads vertically upwards through a ring of nervous tissue, the circumoesophageal commissure, into an expanded stomach, and from this the digestive tube runs back to the anus immediately dorsal to the ventral nerve chain. For Gaskell the infundibulum is the Arthropod oesophagus, the ventricles of the brain are the stomach, and the spinal canal leading back to fuse with the anus at the neurenteric canal is the Arthropod digestive tract. In the Vertebrate a new digestive tract has been formed, probably from a structure corresponding to the branchial chamber of Arthropods. The lateral halves of the ventral nervous system of the Arthropod, where they diverge on either side of the oesophagus, represent the crura cerebri of Vertebrates, whilst the supra-oesophageal ganglia represent the fore-brain. Gaskell has instituted an elaborate comparison, extending to very minute details of structure, and finds remarkable analogies between the organs of Arthropods and structures in the Vertebrates. From the palaeontological side, he points out that at the time when the earliest known Craniates were abundant, large Arthropods, essentially like *Limulus*, were also abundant. He thinks it probable that Vertebrates arose from a dominant invertebrate group, and points to many resemblances in detail between the Silurian Arthropods Palaeostraca and the Craniate Ostracoderms of the same horizon.

VERTICAL (from Lat. *vertex*, highest point), the direction of the line of action of gravity, as determined by the plumb-line. *The angle of the vertical* is the angle between the direction of the plumb-line and that of the earth's centre (see EARTH, FIGURE OF THE).

VERTUE, GEORGE (1684–1756), English engraver and antiquary, was born in St Martin's-in-the-Fields, London, in 1684. At the age of thirteen he was apprenticed to an heraldic engraver, a Frenchman, who failed in three or four years. Vertue then studied drawing at home, and afterwards worked for seven years as an engraver under Michael Vandergucht. He was patronized by Sir Godfrey Kneller, and was one of the first members of the Academy of Painting which that artist instituted in 1711. His plate of Archbishop Tillotson, after Kneller, commissioned by Lord Somers, established his reputation as an engraver; and he was soon in an excellent practice, engraving portraits after Dahl, Richardson, Jervas and Gibson. In portraiture alone he executed over five hundred plates. In 1717 he was appointed engraver to the Society of Antiquaries, and his burin was employed upon many interesting statues, tombs, portraits and other subjects of an antiquarian nature. He died on the 24th of July 1756, and was buried in the cloisters of Westminster Abbey.

From the year 1713 Vertue had been indefatigable in his researches on all matters connected with the history of British art, and had accumulated about forty volumes of memoranda on the subject. These were purchased by Horace Walpole, and form the basis of that author's *Anecdotes of Painting in England*, including an account of Vertue's life and a catalogue of his engravings. Vertue's own literary works include *On Holbein and Gerard's Pictures* (1740); *Medals, Coins, Great Seals, Impressions, from the Elaborate Works of Thomas Simon* (1753); *Catalogue and Description of King Charles the First's Capital Collection of Pictures, Limnings, Statues, &c.* (1757); *Catalogue of the Collection of Pictures belonging to King James II., to which is added a Catalogue of Pictures and Drawings in the Closet of Queen Caroline* (1758); *Catalogue of the Curious Collection of Pictures of George Villiers, Duke of Buckingham* (1758); *Description of the Works of that Ingenious Delineator and Engraver, W. Hollar* (1745).

VERTUMNUS (or VORTUMNUS, "turning," "changing"), in Roman mythology, the god of the changing year with its seasons, flowers and fruits, probably of Italian origin. Like Proteus, he had the power of assuming any shape he pleased, which enabled him to win the love of Pomona (*q.v.*). His shrine and statue (see the well-known description in Propertius iv. 2) were in the Vicus Tuscus, and from his connexion with this busy street he was regarded as having a special interest in trade and barter. At another sanctuary on the slope of the Aventine, sacrifice was offered to him every year on the 13th of August. It is probable that he was of Etruscan origin (see Wissowa, *Religion und Kultus der Römer*, 1902, p. 233).

VERULAMIUM, a Romano-British town situated in the territory of the Catuvellauni, close to the modern St Albans (Hertfordshire). Before the Roman conquest it was probably a native capital: afterwards it received the dignity of a *municipium* (implying municipal status and Roman citizenship). Tacitus tells us that the town was burnt by Boadicea in A.D. 61, but it again rose to prosperity. Its site is still easily recognizable. Its walls of flint rubble survive in stately fragments, and enclose an area of 200 acres. Of the internal buildings little is known. A theatre was excavated in 1847, and parts of the forum were opened by Mr William Page in 1898; both indicate a civilized and cultivated town. The complete uncovering of the site was planned in 1910. (F. J. H.)

VERVET, a Central and South African monkey, known as *Cercopithecus pygerythrus*. It is nearly allied to the grivet (*q.v.*), but distinguished (as indicated by its name) by the presence of a rusty patch at the root of the tail, and by the black (instead of grey) chin, hands and feet.

VERVIERS, a town of Belgium, in the province of Liége, not far from the Prussian frontier, and on the main line from Liége to Aix-la-Chapelle and Cologne. Pop. (1904) 49,168. It is a modern town owing its prosperity to the cloth trade which began here in the 18th century. It is situated on the Vesdre, which flows into the Ourthe a few miles before its junction with the Meuse; and the water of that river is supposed to be especially good for dyeing purposes. As the river water was insufficient to maintain the local industry an artificial reservoir was constructed at La Gileppe on the Hautes Fagnes, and an imposing aqueduct conveys the water stored on these highlands into Verviers. There are also extensive glass factories, but these have suffered from German competition, and many have been closed. A monument to a local celebrity named Chapuis is interesting for the reason that his execution by order of the prince-bishop of Liége was the last act of sovereignty taken by that prelate.

VESICA PISCIS (Fr. *amande mystique*), in architecture, the term given to a pointed oval panel formed by two equal circles cutting each other in their centres; this is a common form given to a panel in which the figure of Christ is represented. It is commonly employed in medieval seals, and especially those of bishops and monastic establishments.

VESOUL, a town of eastern France, capital of the department of Haute-Saone, 236 m. E.S.E. of Paris on the Eastern railway to Belfort. Pop. (1906) 8702. Vesoul is situated between the isolated conical hill of La Motte (1263 ft.) and the river Durgeon. The vine-clad hill, from which there is a fine view of the Jura and Vosges mountains, is crowned by a votive chapel which in 1855 replaced the old fortification. The medieval walls of the town, dating from the 13th and 15th centuries, still exist on its northern side, and in the narrow and winding streets are many old buildings. The church of St George dates from the 18th century. In the pleasant south-eastern quarter are the promenade and the Place de la République, with a monument to the Gardes Mobiles who fell in the war of 1870–71. Vesoul is the seat of a prefect, a tribunal of first instance and a court of assize, and has a lycée for boys, training colleges for both sexes, and a branch of the Bank of France. Distilling and the manufacture of files and tapioca are among the industries. The town is a market for farm-produce and cattle.

Vesoul (*Vesulium Castrum*, *Visolium*, *Vesulum*) is of ancient origin, but in existing records is first mentioned in the 9th century. It was originally a fief of the church of Besançon, and passed afterwards to the house of Burgundy, becoming, in the 13th century, capital of the bailiwick of Amont. The castle was destroyed in the 17th century. The town suffered much during the wars of religion and the Thirty Years' War. Vesoul belonged temporarily to France after the death of Charles the Bold, duke of Burgundy; was returned to the empire when Charles VIII., king of France, broke off his marriage with the daughter of Maximilian, king of the Romans; and again became part of France under Louis XIV. after the peace of Nijmwegen in 1678.

VESPASIAN, in full TITUS FLAVIUS VESPASIANUS, Roman emperor A.D. 70–79, was born on the 18th of November, A.D. 9, in the Sabine country near Reate. His father was a tax-collector and money-lender on a small scale; his mother was the sister of a senator. After having served with the army in Thrace and been quaestor in Crete and Cyrene, Vespasian rose to be aedile and praetor, having meanwhile married Flavia Domitilla, the daughter of a Roman knight, by whom he had two sons, Titus and Domitian, afterwards emperors. Having already served in Germany, in the years 43 and 44, in the reign of Claudius, he distinguished himself in command of the 2nd legion in Britain under Aulus Plautius. He reduced Vectis (Isle of Wight) and penetrated to the borders of Somersetshire. In 51 he was for a brief space consul; in 63 he went as governor to Africa, where, according to Tacitus (ii. 97), his rule was "infamous and odious"; according to Suetonius (*Vesp.* 4), "upright and highly honourable." He went with Nero's suite to Greece, and in 66 was appointed to conduct the war in Judaea, which was threatening general commotion throughout the East, owing to a widely spread notion in those parts that from Judaea were to come the future rulers of the world. Vespasian, who had a strong vein of superstition, was made to believe that he was himself to fulfil this expectation, and all manner of omens and oracles and portents were applied to him. He also found encouragement in Mucianus, the governor of Syria; and although a strict disciplinarian and reformer of abuses, he had a soldiery thoroughly devoted to him. All eyes in the East were now upon him; Mucianus and the Syrian legions were eager to support him; and on the 1st of July 69, while he was at Caesarea, he was proclaimed emperor, first by the army in Egypt, and then by his troops in Judaea. The legions of the East at once took the customary oath of allegiance. Nevertheless, Vitellius, the occupant of the throne, had on his side the veteran legions of Gaul and Germany, Rome's best troops. But the feeling in Vespasian's favour quickly gathered strength, and the armies of Moesia, Pannonia and Illyricum soon declared for him, and made him in fact master of half of the Roman world. They entered Italy on the north-east under the leadership of Antonius Primus, defeated the army of Vitellius at Bedriacum (or Betriacum), sacked Cremona and advanced on Rome, which they entered after furious fighting and a frightful confusion, in which the Capitol was destroyed by fire. The new emperor received the tidings of his rival's defeat and death at Alexandria, whence he at once forwarded supplies of corn to Rome, which were urgently needed, along with an edict or a declaration of policy, in which he gave assurance of an entire reversal of the laws of Nero, especially those relating to treason. While in Egypt he became more and more imbued with superstition, consulting astrologers and allowing himself to be flattered into a belief that he possessed a divine power which could work miracles. Leaving the war in Judaea to his son Titus, he arrived at Rome in 70. He at once devoted his energies to repairing the evils caused by civil war. He restored discipline in the army, which under Vitellius had become utterly demoralized, and, with the co-operation of the senate, put the government and the finances on a sound footing. He renewed old taxes and instituted new, increased the tribute of the provinces, and kept a watchful eye upon the treasury officials. By his own example of simplicity of life, he put to shame the luxury and extravagance of the Roman nobles and initiated in many respects a marked improvement in the general tone of society. As censor he raised the character of the senate, removing unfit and unworthy members and promoting good and able men, among them the excellent Julius Agricola. At the same time he made it more dependent upon the emperor, by exercising an influence upon its composition. He altered the constitution of the praetorian guard, in which only Italians, formed into nine cohorts, were enrolled. In 70 a formidable rising in Gaul, headed by Claudius Civilis, was suppressed and the German frontier made secure; the Jewish War was brought to a close by Titus's capture of Jerusalem, and in the following year, after the joint triumph of Vespasian and Titus, memorable as the first occasion on which a father and his son were thus associated together, the temple of Janus was closed, and the Roman world had rest for the remaining nine years of Vespasian's reign. The peace of Vespasian passed into a proverb. In 78 Agricola went to Britain, and both extended and consolidated the Roman dominion in that province, pushing his arms into North Wales and the Isle of Anglesey. In the following year Vespasian died, on the 23rd of June.

The avarice with which both Tacitus and Suetonius stigmatize Vespasian seems really to have been an enlightened economy, which, in the disordered state of the Roman finances, was an absolute necessity. Vespasian could be liberal to impoverished senators and knights, to cities and towns desolated by natural calamity, and especially to men of letters and of the professor class, several of whom he pensioned with salaries of as much as £800 a year. Quintilian is said to have been the first public teacher who enjoyed this imperial favour. Pliny's great work, the *Natural History*, was written during Vespasian's reign, and dedicated to his son Titus. Some of the philosophers who talked idly of the good old times of the republic, and thus indirectly encouraged conspiracy, provoked him into reviving the obsolete penal laws against this class, but only one, Helvidius Priscus, was put to death, and he had affronted the emperor by studied insults. "I will not kill a dog that barks at me," were words honestly expressing the temper of Vespasian. Much money was spent on public works and the restoration and beautifying of Rome—a new forum, the splendid temple of Peace, the public baths and the vast Colosseum being begun under Vespasian. The roads and aqueducts were repaired, and the limits of the *pomerium* extended.

To the last Vespasian was a plain, blunt soldier, with decided strength of character and ability, and with a steady purpose to establish good order and secure the prosperity and welfare of his subjects. In his habits he was punctual and regular, transacting his business early in the morning, and enjoying his siesta after a drive. He had not quite the distinguished bearing looked for in an emperor. He was free in his conversation, and his humour, of which he had a good deal, was apt to take the form of rather coarse jokes. He could jest, it was said, even in his last moments. "Methinks I am becoming a god," he whispered to those around him. There is something very characteristic in the exclamation he is said to have uttered in his last illness, "An emperor ought to die standing."

See Tacitus, *Histories*; Suetonius, *Vespasian*; Dio Cassius, lxvi.; Merivale, *Hist. of the Romans under the Empire*, chs. 57–60; H. Schiller, *Geschichte der römischen Kaiserzeit*, i. pt. 2; B. W. Henderson, *Civil War and Rebellion in the Roman Empire A.D. 69–70* (1908).

VESPERS (*officium vespertinum*), in the Roman Catholic liturgy, that part of the daily office which follows none (*nona*) and precedes compline (*completorium*). In it the Pater Noster, Ave Maria, Deus in Adjutorium, &c., are followed by five psalms and five antiphons, after which come the "little chapter," the hymn and the verse, which vary according to the season, the Magnificat and its antiphon, and the appropriate collect. In its general features the use of this office can be traced back to a very early date both in the Eastern Church and in the Western. Vespers may be said or sung at any time after midday, and in some circumstances even before it. (See BREVIARY.)

VESPERS, SICILIAN, the revolution of the Sicilians against the Angevin domination, so called because it broke out at the hour of Vespers on Easter Tuesday 1282. Charles I. of Anjou had encountered more resistance in conquering Sicily than on the mainland, as the people were more independent and more strongly attached to the house of Hohenstaufen; and consequently his government was more oppressive and cruel. The officials and the insolent French nobility whom he established in the island rode rough-shod over the privileges of the native aristocracy and the customs of the people, and the natives were ground down by heavy taxes and degrading personal services. The debased currency ruined trade, and the government treated the Sicilians with the utmost contempt. "The outrage of personal service," wrote Amari (*Guerra del Vespro*, ch. iv.), "exceeded the limits of feudalism as well as of the strangest and most brutal caprices. Noble and worthy men were forced to carry viands and wine on their shoulders to the tables of the foreigner, and many young nobles were constrained to turn the spit in his kitchens like scullions or slaves." The administration was more regular, and therefore more unyielding and heartless, than that of the Hohenstaufens, and also more foreign. Hatred of Angevin rule grew day by day, until the people were driven to revolt. According to tradition, the leader of the rising was Giovanni da Procida, a Salernitan noble with Sicilian connexions, who had been in the service of Hohenstaufens, but, having lost position and property after the fall of Conradin, he had taken refuge at the court of Peter III., king of Aragon, and induced him to try to make good his claims on Sicily, which were based on the rights of his queen, Costanza, daughter of Manfred. But as a matter of fact the actual outbreak was a purely unpremeditated popular movement. Charles at that time was making preparations for an attack on the East Roman empire, and extorting more money than ever from the Sicilians in order to meet his expenses. Peter availed himself of the fears which Charles's ambitions were arousing to open negotiations with his various enemies, especially with the Greek emperor, Michael Palaeologus, the Italian Ghibellines, the discontented Sicilian nobles, and perhaps with Pope Nicholas III. Suddenly the people of Sicily, goaded beyond endurance, rose against their rulers, regardless of these various plots. On the 31st of March 1282 a riot broke out in a church near Palermo, in consequence, according to tradition, of the insults of a French soldier towards a Sicilian woman, and a general massacre of the French began. The rising spread to the city, where the republic was proclaimed, and then through the rest of the island; thousands of French men, women and children were butchered (there may be some exaggeration in the wholesale character of the slaughter), and by the end of April the whole of Sicily was in the hands of the rebels. Charles at once led an expedition against the Sicilians and besieged Messina; and although the enemy had been expelled, they would hardly have been able to withstand this new invasion successfully had they not received assistance from Peter of Aragon and their own nobility, whose conspiracy they had so unexpectedly forestalled. This intervention, however, changed the character of the movement, and the free communes which had been proclaimed throughout the island had to submit to the royal prerogatives and to a revived feudalism. Peter, having reached Palermo in September 1282, accepted the Sicilian crown voluntarily offered to him, levied recruits, and declared war on Charles. Hostilities were carried on by land and sea, and the Angevin attacks on Messina were repulsed and followed up by raids on Calabria, where Reggio and other towns declared for King Peter. Charles proposed to settle the Sicilian question by a single combat between himself and Peter; but although the duel was agreed upon it never took place, owing to the mutual distrust of the two rivals. Peter created some discontent by conferring many offices in Sicily on Aragonese and Catalans, but at the parliament of Catania (1283) he undertook at his death to leave Aragon to his son Alphonso and Sicily to his younger son James, so that the two crowns should not be united, an arrangement which fell in with the Sicilians' aspirations towards independence. Pope Martin IV., unlike Nicholas III., threw the whole weight of his authority in favour of the Angevins, excommunicated Peter and the Sicilians, declaring that the former had forfeited even his rights to Aragon, conferred on Charles's expedition to reconquer the island the privileges of a crusade, and levied dimes throughout Christendom to supply the funds. The reason for this uncompromising attitude lies in the papal claim that Sicily was a fief of the Church, a claim which could only be enforced by means of the Angevins. But Charles's fleet was completely destroyed off Malta by that of the Sicilians and Aragonese, commanded by the Calabrese Ruggiero di Lauria (June 1283), and a second fleet met with a similar fate a year later in the bay of Naples, on which occasion Charles's son (afterwards Charles II., *lo Zoppo*) was captured. The Aragonese were now masters of the sea. Risings broke out even in the mainland provinces, and while Charles was preparing for a supreme effort to re-establish his authority he died (1285). Peter died soon after, but the war went on and spread to Aragon, which the Angevins, in virtue of the pope's excommunication of Peter, were trying to conquer. In 1287 the French encountered a fresh naval disaster at the hands of Lauria, and a force which they landed in Sicily was defeated. A two years' truce was now agreed upon, and Charles II. was liberated on his promising to renounce all claims on Aragon; but the pope Nicholas IV., who was determined that no peace should be made unless the Aragonese gave up the island, absolved him from his oath and crowned him king of the Two Sicilies (1289). Alphonso died in 1291, and was succeeded by his brother James, who took possession of the Aragonese crown, leaving his brother Frederick as governor of Sicily, thus uniting the two kingdoms, in violation of King Peter's promises. He then opened negotiations with Pope Boniface VIII. (they had been begun by Alphonso and Nicholas IV.), and eventually agreed to surrender the towns captured in the Neapolitan provinces to Charles II., and hand over Sicily to the Church, actually binding himself to assist in crushing the Sicilians if they resisted; in exchange he was to marry Charles's daughter, Bianca, and to receive Sardinia and Corsica, while Charles's cousin, Charles of Valois, was to renounce his claims on Aragon (1295). This treaty aroused bitter indignation in Sicily, where all classes determined to resist its execution at all costs. They found a leader in Frederick, who, rejecting all the pope's blandishments and bribes, threw in his lot with the Sicilians. For the sequel of the war see under FREDERICK III. of Sicily. Peace was made with the treaty of Caltabellotta in 1302, which left Sicily an independent kingdom under Frederick for that prince's lifetime; and although at his death it was to have reverted to the Angevins, he was actually succeeded by his son, and the island retained its independence for a considerable period. Undoubtedly the Vespers and its consequences revived Sicilian nationalism after the period of degrading Angevin oppression, and with the new dynasty a higher civilization, nearly rivalling that which had flourished under the Hohenstaufens, an improved constitution, and fine military qualities were the outcome.

BIBLIOGRAPHY.—The standard work on the subject is Michele Amari's *Guerra del Vespro* (2 vols. 8th ed., Florence, 1876), which is based on a study of the original authorities, but is too strongly prejudiced against the French; cf. L. Cadier's *Essai sur l'administration du royaume de Sicile par Charles I. et Charles II. d'Anjou* (fasc. 59 of the *Bibliothèque des écoles françaises de Rome et d'Athènes*, Paris, 1891); A. de Saint-Priest, *Histoire de la conquête de Naples par Charles d'Anjou* (Paris, 1847–49); F. Lanzani, *Storia dei communi d'Italia*, lib. v. ch. 3 (Milan, 1882); A. Cappelli's preface to the "Leggenda di Messer Giovanni da Procida," in *Miscellanea di opuscoli inediti o rari dei secoli XIV. XV.* (Turin, 1861). Among the original authorities, Ricobaldo Ferrarese (in Muratori, *Rer. Ital. script.* tom. ix.), the two biographies of Martin IV. (ibid.), Fra Corrado (ibid. tom. i.), the Catalan author of the "Gesta comitum Barcinonensium" (in Barluzio's *Marca Hispanica*, ch. 28) should be mentioned. A considerable list is given in Amari's *Guerra del Vespro*. (L. V.*)

VESPUCCI, AMERIGO (1451–1512), merchant and adventurer, who gave his name of *Amerigo* to the new world as *America*, was born at Florence on the 9th of March 1451. His father, Nastagio (Anastasio) Vespucci, was a notary, and his uncle, Fra Giorgio Antonio Vespucci, to whom he owed his education, was a scholarly Dominican and a friend of Savonarola. As a student Amerigo is said to have shown a preference for natural philosophy, astronomy and geography. He was placed as a clerk in the great commercial house of the Medici, then the ruling family in Florence. A letter of the 30th of December 1492 shows that he was then in Seville; and till the 12th of January 1496 he seems to have usually resided in Spain, especially at Seville and Cadiz, probably as an agent of the Medici. In December 1495, on the death of a Florentine merchant, Juanoto Berardi, established at Seville, who had fitted out the second expedition of Columbus in 1493, and had also undertaken to fit out twelve ships for the king of Spain (April 9th, 1495), Vespucci was commissioned to complete the contract. As Ferdinand, on the 10th of April 1495, recalled the monopoly conceded to Columbus (this order of April 10th, 1495, was cancelled on June 2nd, 1497), "private" exploring now had an opportunity, and adventurers of all kinds were able to leave Spain for the West. Vespucci claims to have sailed with one of these "free-lance" expeditions from Cadiz on the 10th of May 1497. Touching at Grand Canary on the way, the four vessels he accompanied, going thirty-seven days on a west-south-west course, and making 1000 leagues, are said to have reached a supposed continental coast in 16° N., 70° W. from Grand Canary (June 16th, 1497). This should have brought them into the Pacific. They sailed along the coast, says Vespucci, for 80 leagues to the province of Parias (or Lariab), and then 870 leagues more, always to the north-west, to the "finest harbour in the world," which from this description should be in British Columbia or thereabouts. Thence 100 leagues more to north and north-east to the islands of the people called "Iti," from which they returned to Spain, reaching Cadiz on the 15th of October 1498. Still following Vespucci's own statement, he, on the 16th of May 1499, started on a second voyage in a fleet of three ships under Alonzo de Ojeda (Hojeda). Sailing south-west over 500 leagues they crossed the ocean in forty-four days, finding land in 5° S. Thence, encountering various adventures, they worked up to 15° N., and returned to Spain by way of Antiglia (Española, San Domingo), reaching Cadiz on the 8th of September 1500. Entering the service of Dom Manuel of Portugal, Vespucci claims to have taken part in a third American expedition, which left Lisbon on the 10th (or 15th) of May 1501. Vespucci has given two accounts of this alleged third voyage, differing in many details, especially dates and distances. From Portugal he declares that he sailed to Bezeguiche (Cape Verde), and thence south-west for 700 leagues, reaching the American coast in 5° S. on the 7th (or 17th) of August. Thence eastward for 300 (150) leagues, and south and west to 52° S. (or 73° 30′; in his own words, "13° from the antarctic pole," *i.e.* well into the antarctic continent). He returned, he adds, by Sierra Leone (June 10th), and the Azores (end of July), to Lisbon (September 7th, 1502). His second Portuguese (and fourth and last American) voyage, as alleged by him, was destined for Malacca, which he supposed to be in 33° S. (really in 2° 14′ N.). Starting from Lisbon on the 10th of May 1503, with a fleet of six ships, and reaching Bahia by way of Fernando Noronha (?), Vespucci declares that he built a fort at a harbour in 18° S., and thence returned to Lisbon (June 18th, 1504). In February 1505, being again in Spain, he visited Christopher Columbus, who entrusted to him a letter for his son Diego. On the 24th of April 1505, Vespucci received Spanish letters of naturalization; and on the 6th of August 1508 was appointed *piloto mayor* or chief pilot of Spain, an office which he held till his death, at Seville, on the 22nd of February 1512.

If his own account had been trustworthy, it would have followed that Vespucci reached the mainland of America eight days before John Cabot (June 16th against June 24th, 1497). But Vespucci's own statement of his exploring achievements hardly carries conviction. This statement is contained (i.) in his letter written from Lisbon (March or April 1503) to Lorenzo Piero Francesco di Medici, the head of the firm under which his business career had been mostly spent, describing the alleged Portuguese voyage of March 1501–September 1502. The original Italian text is lost, but we possess the Latin translation by "Jocundus interpreter," perhaps the Giocondo who brought his invitation to Portugal in 1501. This letter was printed (in some nine editions) soon after it was written, the first two issues (*Mundus Novus* and *Epistola Albericii de Novo Mundo*), without place or date, appearing before 1504, the third, of 1504 (*Mundus Novus*), at Augsburg. Two very early Paris editions are also known, and one Strassburg (*De Ora Antarctica*) of 1505, edited by E. Ringmann. It was also included in the *Paesi novamente retrovati* of 1507 (Vicenza) under the title of *Novo Mondo da Alb. Vesputio*. The connexion of the new world with Vespucci, thus expressed, is derived from the argument of this first letter, that it was right to call Amerigo's discovery a new world, because it had not been seen before by any one. This prepared the way for the American name soon given to the continent. (ii.) In Vespucci's letter, also written from Portugal (September 1504), and probably addressed to his old schoolfellow Piero Soderini, gonfaloniere of Florence 1502–1512. From the Italian original (of which four printed copies still exist, without place or date, but probably before 1507) a French version was made, and from the latter a Latin translation, published at St Dié in Lorraine in April 1507, and immediately made use of in the *Cosmographiae Introductio* (St Dié, 1507) of Martin Waldseemüller (Hylacomylus), professor of cosmography in St Dié University. Here we have perhaps the first suggestion in a printed book that the newly discovered fourth part of the world should be called "America, because Americus discovered it." Since Alexander von Humboldt discussed the subject in his *Examen critique de l'histoire de la géographie du nouveau continent* (1837), vol. iv., the general weight of opinion (in spite of F. A. de Varnhagen, *Amerigo Vespucci, son caractère, ses écrits. . . sa vie . . .* , Lima, 1865, and other pro-Vespuccian works) has been that Vespucci did not make the 1497 voyage, and that he had no share in the first discovery of the American continent.

VESSEL (O. Fr. *vaissel*, from a rare Lat. *vascellum*, dim. of *vas*, vase, urn), a word of somewhat wide application for many objects, the meaning common to them being capacity to hold or contain something. Thus it is a general term for any utensil capable of containing liquids, and for those tubular structures in anatomy, such as the arteries, veins or lymphatics, which contain, secrete or circulate the blood or lymph. Organs or structures which are largely supplied with vessels are said to be "vascular" (Lat. *vasculum*, another diminutive of *vas*). Vessel (as in French) is also a general term for all craft capable of floating on water larger than a rowing boat. The word is also familiar in Biblical phraseology in the figurative sense of a person regarded as the recipient of some Divine dispensation, a "chosen vessel," or as one into which something is infused or poured, "vessel of wrath."

VESTA (Gr. Ἑστία), the goddess of fire and the domestic hearth. The cults of the Greek Hestia (*q.v.*) and the Latin Vesta, both of which involved the guardianship of an ever-burning sacred fire, are most probably derived from a very early custom, common to a great variety of races in different ages. Among primitive peoples it became the custom for each village to maintain a constant fire for general use, to avoid the necessity of obtaining a spark by friction in case of the accidental extinction of all the village fires.[1] This fire, the central hearth of the village (*focus publicus*), became a sacred symbol of home and family life. The form of the primitive house in which the fire was preserved, probably a round hut made of wattled osiers daubed with clay, appears to have survived both in the circular prytaneum of the Greeks and in the Aedes Vestae (Temple of Vesta) in Rome. To watch this fire would naturally be the duty of unmarried women, and hence may have arisen the Roman order of virgin priestesses, the vestal whose chief duty it was to tend the sacred fire.

The prehistoric method of getting a spark appears to have survived in the rule that, if ever the sacred fire of Vesta did go out, the negligent vestal was to be punished by scourging (Livy xxviii. 11), and the fire rekindled either by friction of dry sticks,[2] or, in later times, by the sun's rays brought to a focus by a concave mirror (Plut. *Numa*, 9). In the prytaneum (*q.v.*) which existed in every Greek state, a different form of cult was developed, though the essential point, the sacred fire, was kept

[1] J. G. Frazer in the *Journal of Philology* (vol. xiv. pp. 145–72), "The Worship of Vesta and its Connexion with the Greek Prytaneum," gives many examples of a similar custom still surviving among various savage races.

[2] An allusion to the earliest method of obtaining fire by rubbing two sticks together is probably contained in the myth of Prometheus, who brought fire to mortals hidden in a hollow wand.

up, just as in the Latin worship of Vesta; and in both cases the fire was extinguished annually at the beginning of the new year, and solemnly rekindled by one of the primitive and hence sacred methods.[1] In Rome this was done on the first day of March, the Latin New Year's Day (Ovid, *Fasti*, iii. 137–45). Among both Greek and early Latin races, at the founding of a new colony, fire was solemnly sent from the prytaneum of the mother colony to kindle a similar sacred fire in the new settlement. Thus we find that, according to tradition, the worship of Vesta in Rome was introduced from Alba Longa (Livy i. 20, and Ovid, *Fasti*, iii. 46), which appears to have been the oldest of the Latin colonies in Latium. The most generally received Latin legend attributes the founding of the Roman temple of Vesta to Numa, who transferred the centre of the cult from Alba, together with the four vestal virgins, its priestesses (Plut. *Numa*, 10). One of the later kings, either Tarquin I. or Servius Tullius, is said to have increased the number to six (Dion. Hal. iii. 67, and Plut. *Numa*, 10), and it is not till the last years of the pagan period that we hear of a seventh vestal having been added (see Ambrose, *Epist.*, ed. Pareus, p. 477; also Plut. *Rom.* and *Cam.*).

The election (*captio*) of the vestal during the early period of Rome was in the hands of the king, and in those of the pontifex maximus under the republic and empire,[2] subject, however, to the following conditions (Aul. Gell. i. 12): (1) the candidate was to be more than six and less than ten years of age; (2) she was to be *patrima* and *matrima*, *i.e.* having both parents alive; (3) free from physical or mental defects; (4) daughter of a free-born resident in Italy. Certain details of the election were arranged subject to the provisions of the Lex Papia, now unknown. The selected child had her hair cut off, and was solemnly admitted by the pontifex maximus, who held her by the hand, and, addressing her by the name *amata*, pronounced an ancient formula of initiation, which is given by Aulus Gellius. In early times there were certain rules by which girls could be excused from serving as vestals, but the honour soon became so eagerly sought that these provisions were practically useless. Vows were taken by the vestal for a period of thirty years, after which she was free to return to private life and even to marry—which she very rarely did (Aul. Gell. vi. 7). This period of thirty years was divided into three decades: during the first the vestal learnt her duties; during the second she practised them; and during the third she instructed the young vestals. The special dignity of chief of the vestals (*virgo vestalis maxima*) was reached in order of seniority. The inscriptions on the pedestals of statues of various *vestales maximae* show that a number of different grades of honour were passed through before reaching the highest dignity or *maximatus*.[3]

The duties of the vestals, besides the chief one of tending the holy fire (Cic. *De Leg.* ii. 8), consisted in the daily bringing of water from the sacred spring of Egeria, near the Porta Capena, to be used for the ceremonial sweeping and sprinkling of the Aedes Vestae.[4] They also offered sacrifices of salt cakes—*muries* and *mola salsa*—and poured on the altar of sacred fire libations of wine and oil, as is represented on the reverses of several first brasses and medallions of the empire. The vestals were bound to offer daily prayers for the welfare of the Roman state, and more especially in times of danger or calamity (Cic. *Pro Font.* 21). They were also the guardians of the seven sacred objects on which the stability of the Roman power was supposed to depend: the chief of these was the Palladium, a rude archaic statue of Pallas, which was said to have been brought by Aeneas from the burning Troy. This sacred object was never shown to profane eyes, but it is represented on the reverse of a coin struck by Antoninus Pius in honour of his deified wife Faustina. Strict observance of the vow of chastity was one of the chief obligations of the vestals, and its breach was punished by burial alive at a place near the Porta Collina known as the Campus Sceleratus (see Livy viii. 15 and 89; Plin. *Ep.* iv. 11; and Suet. *Dom.* 8). Cases of unchastity and its punishment were rare; and, as the evidence against the vestal was usually that of slaves, given under torture, it is probable that in many instances an innocent vestal suffered this cruel death.

The privileges of the vestals and their influential position were very remarkable. They were exempt from any *patria potestas*, except that of the pontifex maximus, their religious father; they could dispose by will of their property, and were in most respects not subject to the Roman laws ("legibus non tenetur," Servius, on Virg. *Aen.* xi. 204; cf. Gaius i. 130, and Dio Cass. lvi. 10). This involved freedom from taxes, and the right to drive through the streets of Rome in carriages (*plostrum* and *currus arcuatus*). Some bronze plates have been found which were once attached to the carriages of vestals; the inscription on one of them runs thus: *Flaviae Publiciae v.v. maximae inmunis in jugo* (see *C.I.L.* vi. 2146–2148; cf. also Prudentius, *Contra Symm.* ii. 1088). They were preceded by a lictor when appearing on state occasions, and enjoyed other semi-royal honours (Plut. *Numa*, 10, and Dio Cass. xlvii. 19). At theatres and other places of amusement they occupied the best seats, except at some of the nude athletic contests, from which they were excluded; they also took an important part in all the grand religious and state ceremonies, as when the pontifex maximus offered sacrifice on the occasion of a triumph before the temple of Capitoline Jupiter. They had power to pardon any criminal they met in the street on his way to execution, provided that the meeting were accidental. The vestals alone shared with the emperors the privilege of intramural burial (Serv. on Virg. *Aen.* xi. 206). During life they were richly dowered by the state (Suet. *Aug.* 31), and had public slaves appointed to serve them (see Tac. *Hist.* i. 43). They were also the guardians of the emperor's will, and of other important documents of state (Suet. *J. Caes.* 83, and *Aug.* 101; Tac. *Ann.* i. 8; Plut. *Anton.* 58; and Appian, *Bell. Civ.* v. 73). Their influence in the appointment to many offices, both religious and secular, appears to have been very great. Many of the statues to the chief vestals which were found in the Atrium Vestae in 1883–1884 have pedestals inscribed with a dedication recording that benefits had been conferred on the donor by the vestalis maxima. Lastly, they lived in a style of very great splendour; their house, the Atrium Vestae, which stood close by the Aedes Vestae, was very large and exceptionally magnificent both in decoration and material (see ROME, *Archaeology*, § "Forum Romanum" and map).

The discovery already mentioned of a number of statues of vestales maximae has thrown new light on the dress of the vestals.[5] With one or two exceptions the costume of these statues is much the same: they have a long sleeveless tunic (*stola*), girdled by the *zona* immediately below the breast. One only wears the *diploidion* over the upper part of her figure. The outer garment is an ample *pallium*, wrapped round the body in a great variety of folds, and in some cases brought over the head like a hood. All seem to have long hair, showing that the process of cutting off the hair at initiation was not repeated. One figure wears the *suffibulum*, a rectangular piece of white cloth bordered by a purple stripe, worn over the head and fastened on the breast by a *fibula*. According to Festus (ed. Müller, p. 348), this sacred garment was worn by the vestals only during the act of sacrificing (see also Varro, *De Ling. Lat.* vi. 21). In all cases the head is closely bound by *vittae*, rope-like twists of woollen cloth, the ends of which usually fall in loops on each shoulder (see Servius on Virg. *Aen.* x. 538).

The *Regia*, the official *fanum* of the pontifex maximus, was adjacent to the vestals' house:—

> "Hic locus est Vestae, qui Pallada servat et ignem;
> Hic fuit antiqui Regia parva Numae."[6]

When Augustus, after his election to the office of pontifex maximus in 12 B.C., moved his place of residence from the Regia to the Palatine, he built a new Aedes Vestae near his palace, in the magnificent Area Apollinis. This appears to have been a copy of the older temple of Vesta. No traces of it now exist; but Pirro Ligorio, in the latter part of the 16th century, made some sketches of what then existed of this second temple, to illustrate his great MS. on Roman antiquities, which is now preserved in the royal library at Turin (see Ovid, *Fasti*, iv. 949–954, and *Metam.* xv. 864). The original course of the Sacra Via passed close to the temple of Vesta; but the road was clumsily built over in the 3rd and 4th centuries.

The chief festival in honour of Vesta, the Vestalia, was held on the 9th of June (Ovid, *Fasti*, vi. 249), after which the temple was closed for five days for a ceremonial cleansing. In private houses the feast was celebrated by a meal of fish, bread and herbs, eaten, not on the usual triclinium, but by the domestic hearth, in front of the effigies of the Dii Penates (Ovid, *Fasti*, vi. 309–310). The feast, inaugurated by Augustus in honour of Vesta Palatina, was held on the 28th of April, the anniversary of its consecration.

With regard to statues of the goddess, though the Greek Hestia was frequently represented in plastic art, yet among the Romans

[1] Fire obtained in this way, that is, "pure elemental fire," was commonly thought to possess a special sanctity. Even throughout the middle ages in Catholic countries, at Easter, when the new year began, the old pagan rite survived (see LIGHTS, CEREMONIAL USE OF.)

[2] From the time of Augustus the emperors themselves held the office of chief pontiff, and with it the privilege of electing the vestals.

[3] These inscriptions are printed in Middleton, *Ancient Rome in 1885*, pp. 200–6, and in *Archaeologia*, xlix. 414–22.

[4] The shrine of Vesta was not a *templum*, in the strict Roman sense, as it was not consecrated by the augurs, its sanctity being far above the necessity of any such ceremony. Other natural springs might be used for the daily sprinkling, but it was forbidden to use water brought in a pipe or other artificial conduit (Tac. *Hist.* iv. 53); see also Guhl and Koner, *Das Leben der Griechen und Römer* (Eng. trans. by F. Hueffer, 1875).

[5] These statues appear to have been the work of a privileged class of sculptors, who enjoyed the title of "fictores virginum vestalium"—an honour which is recorded in some of the dedicatory inscriptions on the pedestals.

[6] Ovid, *Tristia*, iii. 29.

Vesta appears to have been rarely so treated. The Athenian prytaneum contained a statue of Hestia. But there was no effigy in the Roman temple of Vesta, although one is commonly shown on reverses of coins which have a representation of the temple, and it appears to have been commonly thought in Rome that a statue of Vesta did exist inside her shrine—a mistake which Ovid corrects (*Fasti*, vi. 297–300). No Roman statue now known can be certainly considered to represent Vesta, though a very beautiful standing figure of a female with veiled head (in the Torlonia collection) has, with some probability, had this name given to it.

The worship of Vesta appears to have died out slowly in the 4th century, after the adoption of Christianity as the state religion by Constantine, and in 382 Gratian confiscated the Atrium Vestae. Zosimus (*Hist. Nov.* v. 38) tells an interesting story of a visit made to it at the end of the 4th century by Serena, the wife of the Vandal Stilicho, who took a valuable necklace from one of the statues, in spite of the remonstrances of an aged woman, the last survivor of the vestal virgins. Soon after that time the building appears to have fallen into decay, its valuable marble linings and other ornaments having been stripped from its walls.

AUTHORITIES.—For the Atrium and the Aedes Vestae see ROME, *Archaeology* (footnote *ad loc.*). See also Wissowa, *Relig. und Kultus der Römer* (1902) and authorities under HESTIA. (J. H. M.; X.)

VESTERÅS, or WESTERÅS, a town and bishop's see of Sweden, capital of the district (*län*) of Vestmanland, on a northern bay of Lake Mälar, 60 m. N.W. by W. of Stockholm by rail. Pop. (1900) 11,999. It is a considerable industrial centre and an important lake port. Its Gothic cathedral, rebuilt by Birger Jarl on an earlier site, and consecrated in 1271, was restored in 1850–1860, and again in 1896–1898. The episcopal library contains the valuable collection of books which Oxenstjerna, the chancellor of Gustavus Adolphus, brought away from Mainz near the end of the Thirty Years' War. A castle commands the town from an eminence; it was captured by Gustavus Vasa and rebuilt by him, and again in the 17th century, and remains the seat of the provincial government. Here Eric XIV., whose tomb is in the cathedral, was confined (1573–1575). Several national diets were held in this town, the most notable being those of 1527, when Gustavus Vasa formally introduced the Reformation into Sweden, and 1544, when he had the Swedish throne declared hereditary in his family. The original name of the town was Vestra Aros ("western mouth"), in distinction from Östra Aros, the former name of Upsala.

VESTIBULE (from Lat. *vestibulum*), the architectural term given to an antechamber next to the entrance and preceding the hall; it is also applied to the anteroom of any large apartment. The word is connected, like Vesta (*q.v.*), with the Sanscrit root *vas-*, to dwell, inhabit. In medieval Latin it was occasionally used, instead of *vestiarium*, for a vestry (see Du Cange, *Gloss. med. lat.*, s.v.), which is derived from Lat. *vestis*, clothing.

VESTINI, an ancient Sabine tribe which occupied the eastern and northern bank of the Aternus in central Italy, entered into the Roman alliance, retaining its own independence, in 304 B.C., and issuing coins of its own in the following century. A northerly section round Amiternum near the passes into Sabine country probably received the Caerite franchise soon after. In spite of this, and of the influence of Hadria, a Latin colony founded about 290 B.C. (Livy, *Epil.* xi.), the local dialect, which belongs to the north Oscan group, survived certainly to the middle of the 2nd century B.C. (see the inscriptions cited below) and probably until the Social War. The oldest Latin inscriptions of the district are *C.I.L.* ix. 3521, from Furfo with Sullan alphabet, and 3574, "litteris antiquissimis," but with *couraverunt*, a form which, as intermediate between *coir-* or *coer-* and *cur-*, cannot be earlier than 100 B.C. (see LATIN LANGUAGE). The latter inscription contains also the forms *magist[r]es* (nom. pl.) and *ueci* (gen. sing.), which show that the Latin first spoken by the Vestini was not that of Rome, but that of their neighbours the Marsi and Aequi (*qq.v.*). The inscription of Scoppito shows that at the time at which it was written the upper Aternus valley must be counted Vestine, not Sabine, in point of dialect.

See further PAELIGNI and SABINI, and for the inscriptions and further details, R. S. Conway, *The Italic Dialects*, pp. 258 ff., on which this article is based. (R. S. C.)

VESTMENTS. The word "vestment" (Lat. *vestimentum*, fr. *vestire*, to clothe), meaning generally simply an article of clothing, is in the usage of the present day practically confined to the ceremonial garments worn in public worship; in this sense it may be used equally of the robes or "ornaments" of the ministers or priests of any religion. Ecclesiastical vestments, with which the present article is solely concerned, are the special articles of costume worn by the officers of the Christian Church "at all times of their ministration"—to quote the Ornaments Rubric of the English Book of Common Prayer, *i.e.* as distinct from the "clerical costume" worn in everyday life. Ecclesiastical vestments may again be divided into two categories: (1) liturgical vestments, (2) non-liturgical vestments. Liturgical vestments, as their name implies, are those which are especially associated with the various functions of the liturgy. Of these again, according to the fully developed rules of the Catholic Church, there are three classes: (1) vestments worn only at the celebration of mass— chasuble, maniple, pontifical gloves, pontifical shoes, the pallium and the papal fanone and *subcinctorium*; (2) vestments never worn at mass, but at other liturgical functions, such as processions, administration of the sacraments, solemn choir services, *i.e.* cope and surplice; (3) vestments used at both—alb, amice, girdle, stole, dalmatic, tunicle. Non-liturgical vestments are those, *e.g.* cappa magna, rochet, which have no sacral character, have come into use from motives of convenience or as insignia of dignity, and are worn at secular as well as ecclesiastical functions.

In the controversies as to the interpretation of the Anglican "Ornaments Rubric" (see below) the term "vestments" has been applied particularly to those worn at the celebration of mass, which is what is meant when it is said that "the vestments" are worn at such and such a church. This restriction of the term has some historical justification: in the First Prayer Book of Edward VI. the word "vestment" is used as synonymous with but one liturgical garment—the chasuble, the "mass vestment" *par excellence*; in the Prayer Book of 1559 "vestments" are eliminated altogether, "ornaments" being substituted as a more comprehensive term. As to the use of the word, it must be further stated that it is also technically applied to altar cloths, the altar being "vested" in frontal (*antependium*) and super-frontal (see ALTAR).

The subject of ecclesiastical vestments is not only one of great interest from the point of view of archaeology and art, but is also of importance, in so far as certain "ornaments" have become historically associated with certain doctrines on which the opinion of the Christian world is sharply divided. The present article can only give a brief outline of a subject as intricate as it is vast, frequently also extremely obscure, and rendered still more obscure by the fact that those who have applied themselves to it have too often done so in anything but a scientific spirit. It will deal briefly (1) with the general idea and the historical evolution of ecclesiastical vestments, (2) with the vestments as at present worn (*a*) in the Roman Catholic Church, (*b*) in the Oriental Churches, (*c*) in the Reformed Churches, (*d*) in the Anglican Church. The more important vestments are dealt with in some detail under their separate headings; here it will only be necessary to give short descriptions of those which cannot be conveniently treated separately.

1. *The Origin and Idea of Ecclesiastical Vestments.*—The liturgical vestments of the Catholic Church, East and West, are not, as was at one time commonly supposed, borrowed from the sacerdotal ornaments of the Jewish ritual, although the obvious analogies of this ritual doubtless to a certain extent determined their sacral character; they were developed independently out of the various articles of everyday dress worn by citizens of the Graeco-Roman world under the Empire. The officers of the Church during the first few centuries of its existence were content to officiate in the dress of civil life, though their garments were expected to be scrupulously clean and of decent quality. The few scattered references in contemporary records to the dress of the clergy all point to this as the only recognized rule.

Thus in the 37th of the so-called "Canons of Hippolytus" we read: "As often as the bishops would partake of the Mysteries, the presbyters and deacons shall gather round him clad in white, quite particularly clean clothes, more beautiful than those of the rest of the people." Thus, too, St Jerome, in his commentary on Ezek. xliv. 19, says that "We, too, ought not to enter the Holy of Holies in our everyday garments . . . when they have become defiled from the use of ordinary life, but with a clean conscience, and in clean garments, hold in our hands the Sacrament of the Lord."

When, in the year 289, St Cyprian was led to martyrdom, he wore, according to Eusebius (*Hist. eccles.* iv. cap. 11), an under tunic (*linea*), an upper tunic (*dalmatica*, *tunica*) and mantle (*lacerna*, *byrrus*). This was the ordinary type of the civil costume of the time. The tunica, a loose sack-like tunic with a hole for the head, was the innermost garment worn by all classes of Roman citizens under the republic and empire. It was either sleeveless (*colobium*) or sleeved (*tunica manicata* or *manuleata*), and originally fell about to the knee, but later on reached to the ankles (*tunica talaris*). St Augustine (*De doctr. christ.* iii. cap. 10, n. 20) says that to wear *talares et tunicas manicatas* was a disgrace among the ancient Romans, but that in his own day it was no longer so considered in the case of persons of good birth. The tunica was originally of white wool, but in the 3rd century it began to be made of linen, and from the 4th century was always of linen. About the 6th century the long *tunica alba* went out of fashion in civil life, but it was retained in the services of the Church and developed into the various forms of the liturgical alb (*q.v.*) and surplice (*q.v.*). The *tunica dalmatica* was a long, sleeved upper tunic, originating, as its name implies, in Dalmatia, and first becoming fashionable at Rome in the 2nd century; it is the origin of the liturgical dalmatic and tunicle (see DALMATIC). Another over-dress of the Romans was the *paenula*, a cloak akin to the *poncho* of the modern Spaniards and Spanish Americans, *i.e.* a large piece of stuff with a hole for the head to go through, hanging in ample folds round the body. This was originally worn only by slaves, soldiers and other people of low degree; in the 3rd century, however, it was adopted by fashionable people as a convenient riding or travelling cloak; and finally, by the sumptuary law of 382 (*Cod. Theod.* xiv. 10, 1, *de habitu . . . intra urbem*) it was prescribed as the proper everyday dress of senators, instead of the military chlamys, the toga being reserved for state occasions. This was the origin of the principal liturgical vestment, the chasuble (*q.v.*).

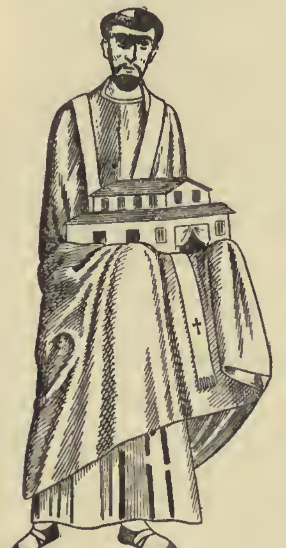

FIG. 1.—Pope Honorius (d. 638). From a mosaic in S. Agnese in Rome.

As late as the 6th century these garments were common both to the clergy and laity, and, so far as their character was concerned, were used both in the liturgy and in everyday life. Meanwhile, however, a certain development had taken place. By the 4th century the garments worn at liturgical functions had been separated from those in ordinary use, though still identical in form. It is in the 4th century, too, that the first distinctive vestment makes its appearance, the ὠμοφόριον worn by all bishops in the East; in the 5th century we find this in use at Rome under the name of *pallium* (*q.v.*), as the distinctive ornament of the pope (see fig. 1). About the same time the *orarium*, or stole (*q.v.*), becomes fixed in liturgical use. The main development and definition of the ecclesiastical vestments, however, took place between the 6th and the 9th centuries. The secular fashions altered with changes of taste; but the Church retained the dress with the other traditions of the Roman Empire. At Rome, especially, where the popes had succeeded to a share of the power and pretensions of the Caesars of the West, the accumulation of ecclesiastical vestments symbolized a very special dignity: in the second quarter of the 9th century the pope, when fully vested, wore a *camisia* girdled, an alb (*linea*) girdled, an amice (*anagolaium*), a tunicle (*dalmatica minor*), a dalmatic (*dalmatica major*), stole (*orarium*), chasuble (*planeta*) and pallium. With the exception of the pallium, this was also the costume of the Roman deacons. By this time, moreover, the liturgical character of the vestments was so completely established that they were no longer worn instead of, but over, the ordinary dress.

Hitherto the example of the Roman Church had exercised no exclusive determining influence on ritual development even in the West. The popes had, from time to time, sent the pallium or the dalmatic—specifically Roman vestments—as gifts of honour to various distinguished prelates; Britain, converted by a Roman mission, had adopted the Roman use, and English missionaries had carried this into the newly Christianized parts of Germany; but the great Churches of Spain and Gaul preserved their own traditions in vestments as in other matters. From the 9th century onwards, however, this was changed; everywhere in the West the Roman use ousted the regional uses.

This change synchronized with the revival of the Western Empire under Charlemagne, a revival which necessarily gave an impulse to the claims of the see of Rome. The adoption of the Roman liturgical dress had, however, at most an indirect connexion with these claims. Charlemagne was active in prescribing the adoption of the Roman use; but this was only as part of his general policy in the organization of his empire. A renovation of the Gallican Church was not the least crying need; and, in view of the confusion of rites (Gallican, Gothic, Roman, Ambrosian) in the Frankish empire, Charlemagne recognized that this innovation could only be effectually carried out by a closer connexion with Rome in ritual as in other matters. Charlemagne's activity in this respect was, in effect, but the completion of a process that had been going on since the 6th century. Whatever effect the reinvigoration of the papacy may have had in hastening the process, the original impulse towards the adoption of the Roman rite had proceeded, not from Rome, but from Spain and Gaul; it was the natural result of the lively intercourse between the Churches of these countries and the Holy See. Nor was the process of assimilation by any means one-sided. If Spain and Gaul borrowed from Rome, they also exercised a reciprocal influence on the Roman use; it is interesting to note in this connexion, that of the names of the liturgical vestments a very large proportion are not of Roman origin, and that the non-Roman names tended to supersede the Roman in Rome itself.[1]

FIG. 2.—Stigand, Archbishop of Canterbury (1052–1070); from the Bayeux Tapestry. Note the absence of the mitre, the chasuble short or tucked up in front, the maniple still carried in the left hand.

[1] Apart from the archiepiscopal pallium, the Churches of Spain and Gaul had need to borrow from Rome only the dalmatic, maniple and liturgical shoes. On the other hand, it was from Spain and Gaul that Rome probably received the *orarium* (stole) as an ensign of the major orders. Father Braun, to whose kindness the writer is indebted for the above account of the causes of the ritual changes in the Carolingian epoch, adds that the papacy was never narrow-minded in its attitude towards local rites, and that it was not until the close of the middle ages, when diversity had become confusion and worse, that it began to insist upon uniformity. Even then it allowed those rites to survive which could prove a tradition of 200 years.

The period between the 9th and the 13th centuries is that of the final development of the liturgical vestments in the West. In the 9th century appeared the pontifical gloves; in the 10th, the mitre; in the 11th, the use of liturgical shoes and stockings was reserved for cardinals and bishops. By the 12th century, mitre and gloves were worn by all bishops, and in many cases they had assumed a new ornament, the *rationale*, a merely honorific decoration (supposed to symbolize doctrine and wisdom), sometimes of the nature of a highly ornamental broad shoulder collar with dependent lappets; sometimes closely resembling the pallium; rarely a "breast-plate" on the model of that of the Jewish high priest.[1] This elaboration of the pontifical vestments was contemporaneous with, and doubtless partly determined by, the assimilation of the bishops during those centuries to the type of the great feudal nobles whose ambitions and love of pomp they shared.

In an age when, with the evolution of the feudal organization of society, even everyday costume was becoming a uniform, symbolizing in material and colour the exact status of the wearer, it was natural that in the parallel organization of the Church the official vestments should undergo a similar process of differentiation and definition. With this process, which in all its essential features was completed in the 11th century, doctrinal developments had little or nothing to do, though from the 9th century onwards liturgiologists were busy expounding the mystic symbolism of garments which, until their imagination set to work, had for the most part no symbolism whatever (see below). Yet in view of later controversies, the changes made during this period, notably in the vestments connected with the mass, are not without significance. Hitherto the chasuble had been worn indifferently by all ministers at the eucharist, even by the acolytes; it had been worn also at processions and other non-liturgical functions; it was now exalted into the mass vestment *par excellence*, worn by the celebrant only, or by his immediate assistants (deacon and subdeacon) only on very special occasions. New vestments were devised to take the place, on less solemn occasions, of those hallowed by association with the holy sacrifice; thus the processional cope (*q.v.*) appeared in the 11th century and the surplice (*q.v.*) in the 12th. A change, too, came over the general character of vestments. Up to the 9th century these had been very plain, without ornament save such traditional decorations as the *clavi* of the dalmatic; what splendour they had was due to their material and the ample folds of their draperies. But from this time onwards they tend to become more and more elaborately decorated with embroidery and jeweller's work (see, *e.g.* the articles CHASUBLE and COPE).

From Braun's *Liturgische Gewandung*, by permission of B. Herder.

FIG. 3.—Monumental Figure of Bishop Johannes of Lübeck (d. 1350) in Lübeck Cathedral.

Very significant, too, is the parting of the ways in the development of liturgical vestments in the East and West. During the first centuries both branches of the Church had used vestments substantially the same, developed from common originals; the alb, chasuble, stole and pallium were the equivalents of the στιχάριον, φενόλιον, ὠράριον and ὠμοφόριον. While, however, between the 9th and 13th centuries, the Western Church was adding largely to her store of vestments, that of the East increased her list by but three, the ἐγχείριον and ἐπιμανίκια (see MANIPLE) and the σάκκος (see DALMATIC). The living force of development in the Latin Church was symbolized in her garments; the stereotyped orthodoxy of the Greek Church in hers. With the exception of the mitre, introduced in the 15th or 16th century, the liturgical costume of the Eastern clergy remains now practically what it was in the 9th century.

In the Western Church, though from the 9th century onwards the Roman use had been the norm, considerable alterations continued to be made in the shape and decoration of the liturgical vestments, and in this respect various Churches developed different traditions (see, *e.g.* CHASUBLE). The definition of their use by the various orders of the clergy in the several liturgical functions, however, was established by the close of the 13th century and still continues in force. Before discussing the changes made in the various Reformed Churches, due to the doctrinal developments of the 16th century, we may therefore give here a list of the vestments now worn by the various orders of clergy in the Roman Catholic Church and the Oriental Churches.

FIG. 4.—Dr Henry Sever (d. 1471). From a brass in the chapel of Merton College, Oxford. He is vested in surplice, stole and cope.

FIG. 5.—Thomas Cranley, Archbishop of Dublin (d. 1417). From a brass in New College Chapel, Oxford. In addition to the vestments shown in fig. 3 he wears the archiepiscopal pallium.

Roman Catholic Church.—As the sacrifice of the mass is the central mystery of the Catholic faith, so the seven orders of the hierarchy culminate in that of priest, who alone is empowered to work the daily miracle of the altar (see ORDER, HOLY). The vestments worn by the priest when celebrating mass are then the most important. The cassock (*q.v.*), which must always be worn under the vestments, is not itself a liturgical garment. Over this the priest, robing for mass, puts on the amice, alb, girdle (*cingulum*), stole, maniple and chasuble. Taking the other orders downwards: deacons wear amice, alb, girdle, stole, maniple[2] and dalmatic; subdeacons, amice, alb, girdle, maniple and tunicle; the vestment proper to the minor orders, formerly the alb, is now the surplice or cotta. Bishops, as belonging to the order of priesthood with completed powers, wear the same vestments as the priests, with the addition of

[1] The *rationale* is worn only over the chasuble. It is now used only by the bishops of Eichstätt, Cracow, Paderborn and Toul, by the special concession of various popes. See Braun, *Liturg. Gewandung*, pp. 676–700.

[2] The stole and maniple alone are symbolical of order, *i.e.* of the relation to the sacrifice of the mass.

the pectoral cross, the pontifical gloves, the pontifical ring, the liturgical sandals and caligae, a tunicle worn over the stole and under the chasuble, and the mitre (see fig. 3). Archbishops, on solemn occasions, wear the pallium over the chasuble (see fig. 5). Bishops also carry a pastoral staff (*q.v.*), as symbol of their pastoral office. Finally, the pope, when celebrating mass, wears the same vestments as an ordinary bishop, with the addition of the *subcinctorium* (see ALB), a dalmatic, worn over the tunicle and under the chasuble, and the *orale* or *fanone* (see AMICE). It should be noted that the *liturgical* head-dress of the pope is the mitre, not the tiara, which is the symbol of his supreme office and jurisdiction (see TIARA).

From a photograph by Conjugi Cane, Rome.

FIG. 6.—Pope Leo XIII. in his Vestments as Supreme Pontiff.

Of the liturgical vestments not immediately or exclusively associated with the sacrifice of the mass the most conspicuous are the cope and surplice. The biretta, too, though not in its origin or in some of its uses a liturgical vestment, has developed a distinctly liturgical character (see BIRETTA). Besides the strictly liturgical vestments there are also numerous articles of costume worn at choir services, in processions, or on ceremonial occasions in everyday life, which have no sacral character; such are the almuce (*q.v.*), the *cappa* and *mozzetta* (see COPE), the rochet (*q.v.*), the *pileolus*, a skull-cap, worn also sometimes under mitre and tiara. These are generally ensigns of dignity; their form and use varies in different Churches, and they often represent special privileges conferred by the popes, *e.g.* the *cappa* of the Lateran basilica worn by the canons of Westminster cathedral, or the almuce worn, by concession of Pope Pius IX., by the members of the Sistine choir.

The character of the vestments, the method of putting them on, and the occasions on which they are severally to be worn, are regulated with the minutest care in the Missal and the *Caeremoniale*.

Oriental Churches.—As already stated, the vestments of the great historical Churches of the East are derived from the same Graeco-Roman originals as those of the West, but in contradistinction to the latter they have remained practically stereotyped, both in character and number, for a thousand years; in the East, however, even more than in the West the tendency to gorgeous ornamentation has prevailed.

An Orthodox bishop, vested for the holy liturgy, wears over his cassock—(1) the *στιχάριον*, or alb (*q.v.*); (2) the *ἐπιτραχήλιον*, or stole (*q.v.*); (3) the *ζώνη*, a narrow stuff girdle clasped behind, which holds together the two vestments above named; (4) the *ἐπιμανίκια*, liturgical cuffs, corresponding, possibly, to the pontifical gloves of the West;[1] (5) the *ἐπιγονάτιον*, a stiff lozenge-shaped piece of stuff hanging at the right side by a piece of riband from the girdle or attached to the *σάκκος*, the equivalent of the Western maniple (*q.v.*); (6) the *σάκκος*, like the Western dalmatic (*q.v.*), worn instead of the *φαινόλιον*, or chasuble; (7) the *ὠμοφόριον*, the equivalent of the Western pallium (*q.v.*). Besides these, the bishop also wears a pectoral cross (*ἐγκόλπιον*) and a medal containing a relic (*πανάγια*). He also has a mitre (*q.v.*), and carries a crozier (*δικανίκιον*), a rather short staff ending in two curved branches decorated with serpents' heads, with a cross between them.

The vestments of a priest are the sticharion, epitrachelion, girdle, epimanikia and phainolion (see CHASUBLE). He wears all these vestments only at the celebration of the eucharist and on other very solemn occasions; at other ministrations he wears only the epitrachelion and phainolion over his cassock. A dignitary in priest's orders is distinguished by wearing the epigonation; and in Russia the use of the mitre is sometimes conceded to distinguished priests by the tsar. The deacon wears the sticharion, without a girdle, the epimanikia and the orarion (*ὠράριον*, Lat. *orarium*, see STOLE) hanging over his left shoulder. The lesser orders wear a shorter sticharion and an orarion wound round it.

FIG. 7.—An Orthodox Eastern Patriarch in full Pontificals.

On less solemn occasions bishops wear the mandyas (*μανδύας*), a cope-like garment fastened at the lower corners as well as at the neck, and the kalimaukion (*καλημαύκιον*), a tall, brimless hat, with a veil hanging down behind, and, in place of the *διακόνιον* they carry a short staff with an ivory cross-piece. The kalimaukion is also worn by the other clergy in ordinary life, and with their vestments at processions, &c.

The general character of the vestments is much the same in the other Oriental rites. The sticharion answers to the Armenian *shabik*, the Nestorian *kutina*, the Coptic *tuniah* or *stoicharion*; the epimanikia to the Arm. *pasban* (which, however, resembles rather the Latin maniple), the Nestorian *zando*, and the Coptic *kiman*; the epitrachelion to the Arm. *por-urar*, Syrian *uroro*, Coptic *batrashil*; the girdle to the Arm. *kodi*, Nestorian *zunro*; the phainolion to the Nestorian *phaino* and Arm. *shurtshar*, both of which are, however, cope-shaped.[2] Armenian priests, besides, wear a mitre (see MITRE, fig. 3), and a collar-like ornament probably derived from the apparel of the Western amice (*q.v.*). The liturgical handkerchief, which in the Greek Church has become the epigonation, has retained its original form in the Armenian.

The Liturgical Colours.—In another respect the vestments of the Eastern differ from those of the Western Church. In the East there is no sequence of liturgical colours, nor, indeed, any definite sense of liturgical colour at all; the vestments are usually white or red, and stiff with gold embroidery. In the West the custom, long universal, of marking the seasons of the ecclesiastical year and the more prominent fasts and festivals by the colour of the vestments of clergy and altar dates, approximately, from the 12th century: the subject is mentioned (*c.* 1200) in the treatise of Innocent III., *De sacro altaris mysterio* (cap. 10), where the rules are laid down which are still essentially those of the Roman Church,[3] though the liturgical colours were only four, violet belonging to the category of black—as that of mourning. Custom in this respect was, however, exceedingly varied for a long time, numerous important Churches having their own "uses," and it was not until the time of the Reformation that the Roman use was fixed and became the norm of the Churches of the Roman obedience.

According to the rubric of the Roman Missal (*tit.* xviii.) the liturgical colours are five: white, red, green, violet, black. Though, in the embroidery of vestments, many colours may be used, these five above named must severally give the dominant tone of colour on the occasions for which they are appointed. Gold brocades or cloth-of-gold may, however, be substituted for red, green and white, and silver for white. The following is a list of the occasions to which the various colours are appropriated:—

White.—Trinity Sunday, all festivals of Christ (except those connected with the Passion), festivals of the Blessed Virgin, of the Holy Angels and Confessors, of holy virgins and women (not being martyrs), nativity of St John the Baptist, festivals of the chains of St Peter and of his see (*cathedra Petri*), Conversion of St Paul, All Saints, consecration of churches and altars, anniversary of election and coronation of popes, and of election and consecration of bishops. White is also worn during the octaves of these festivals, on ordinary days (for which no special colour is provided) between Easter and Whitsuntide, at certain special masses connected with the saints falling under the above category, and at bridal masses.

[1] This is the view of Dr Adrian Fortescue (*The Orthodox Eastern Church*, p. 406); according to Braun (*Lit. Gewandung*, p. 100) they were originally merely the ornamental cuffs (λωρία) of the episcopal sticharion, which were detached for purposes of convenience.

[2] By the sub-committee of Convocation in their *Report* (1908) these vestments are wrongly classed as copes, *i.e.* as derived not from the *paenula* but from the *lacerna* or *birrus* (see COPE, footnote).

[3] The Church of the Holy Sepulchre at Jerusalem seems already to have had its canon of liturgical colours.

White is also the colour proper to sacramental processions, and generally to all devotions connected with the exposition of the Blessed Sacrament. At baptisms the priest wears a violet stole during the first part of the service, *i.e.* the exorcization then changes it for a white one. White is worn at the funerals of children.

Red.—Saturday before Whitsunday, Whitsunday and its octave; all festivals in commemoration of the sufferings of Christ, *i.e.* festival of the instruments of the Passion, of the Precious Blood, of the invention and elevation of the Cross; all festivals of apostles, except those above noted; festivals of martyrs; masses for a papal election; the Feast of the Holy Innocents, when it falls on a Sunday (violet if on a week-day), and its octave (always red). In England red vestments are worn at the mass (of the Holy Spirit) attended by the Roman Catholic judges and barristers at the opening of term, the so-called "Red Mass."

Green.—Sundays and week-days between Epiphany and Septuagesima, and between Trinity and Advent, except festivals and their octaves and Ember days.

Violet.—Advent; the days between Septuagesima and Maundy Thursday; vigils that fall on fast days, and Ember days, except the vigil before Whitsunday (red) and the Ember days in Whitsun week (red). Violet vestments are also worn on days of intercession, at votive masses of the Passion, at certain other masses of a pronouncedly intercessory and penitential character, at intercessory processions, at the blessing of candles on Candlemas Day, and at the blessing of the baptismal water. A violet stole is worn by the priest when giving absolution after confession, and when administering Extreme Unction.

Black.—Masses for the dead and funeral ceremonies of adults; the mass of the pre-sanctified on Good Friday.[1]

Benediction of Vestments.—In the Roman Catholic Church the amice, alb, girdle, stole, maniple, chasuble must be solemnly blessed by the bishop or his delegate, the prayers and other forms to be observed being set forth in the *Pontificale* (see BENEDICTION). Other vestments—*e.g.* dalmatic, tunicle, surplice—are sometimes blessed when used in connexion with the sacrifice of the mass, but there is no definite rule on the subject. The custom is very ancient, Father Braun giving evidence as to its existence at Rome as early as the 6th century (*Liturg. Gewandung*, p. 760, &c.).

Mystic Meaning of Vestments.—It is clear from what has been said above that the liturgical vestments possessed originally no mystic symbolic meaning whatever; it was equally certain that, as their origins were forgotten, they would develop such a symbolic meaning. The earliest record of any attempt to interpret this symbolism that we possess is, so far as the West is concerned, the short exposition in the *Explicatio Missae* of Germanus, bishop of Paris (d. 576), the earliest of any elaboration that of Hrabanus Maurus (d. 856). From the latter's time onward a host of liturgists took up the theme, arguing from the form, the material, the colour and the fashion of wearing the various garments to symbolical interpretations almost as numerous as the interpreters themselves. The *Report* of the five bishops divides them into three schools: (1) the *moralizing school*, the oldest, by which—as in the case of St Jerome's treatment of the Jewish vestments—the vestments are explained as typical of the virtues proper to those who wear them; (2) the *Christological school*, *i.e.* that which considered the minister as the representative of Christ and his garments as typical of some aspects of Christ's person or office—*e.g.* the stole is his obedience and servitude for our sakes; (3) the *allegorical school*, which treats the priest as a warrior or champion, who puts on the amice as a helmet, the alb as a breastplate, and so on. We cannot even outline here the process of selection by which the symbolic meanings now stereotyped in the Roman Pontifical were arrived at. These are taken from the various schools of interpretation mentioned above, and are now formulated in the words used by the bishop when, in ordaining to any office, he places the vestment on the ordinand with the appropriate words, *e.g.* "Take the amice, which signifies discipline in speech," while other interpretations survive in the prayers offered by the priest when vesting, *e.g.* with the amice, "Place on my head the helmet of salvation," &c. For the symbolic meanings of the various vestments see the separate articles devoted to them.

[1] In the Anglican Church, in the numerous cases when the liturgical colours are used, these generally follow the Roman use, which was in force before the Reformation in the important dioceses of Canterbury, York, London and Exeter. Some Churches, however, have adopted the colours of the use of Salisbury (Sarum). The red hangings of the Holy Table, usual where the liturgical colours are not used, are also—like the cushions to support the service books—supposed to be a survival of the Sarum use.

Protestant Churches.—In the Protestant Churches[2] the custom as to vestments differs widely, corresponding to a similar divergence in tradition and teaching. At the Reformation two tendencies became apparent. Luther and his followers regarded vestments as among the *adiaphora*, and in the Churches which afterwards came to be known as "Lutheran" many of the traditional vestments were retained. Calvin, on the other hand, laid stress on the principle of the utmost simplicity in public worship; at Geneva the traditional vestments were absolutely abolished, and the Genevan model was followed by the Calvinistic or "Reformed" Churches throughout Europe. The Church of England, in which the Lutheran and Calvinistic points of view struggled for the mastery, a struggle which resulted in a compromise, is separately dealt with below. At the present day the Lutheran Churches of Denmark and Scandinavia retain the use of alb and chasuble in the celebration of the eucharist (stole, amice, girdle and maniple were disused after the Reformation), and for bishops the cope and mitre. The surplice is not used, the ministers conducting the ordinary services and preaching in a black gown, of the 16th-century type, with white bands or ruff. In Germany the Evangelical Church (outcome of a compromise between Lutherans and Reformed) has, in general, now discarded the old vestments. In isolated instances (*e.g.* at Leipzig) the surplice is still worn; but the pastors now usually wear a barret cap, a black gown of the type worn by Luther himself, and white bands. In Prussia the superintendents now wear pectoral crosses (instituted by the emperor William II.). In the "Reformed" Churches the minister wears the black "Geneva" gown with bands. It is to be noted, however, that this use has been largely discontinued in the modern "Free" Churches. On the other hand, some of these have in recent times adopted the surplice, and in one at least (the Catholic Apostolic Church) the traditional Catholic vestments have been largely revived.

Anglican Church.—The subject of ecclesiastical vestments has been, ever since the Reformation, hotly debated in the Church of England. For a hundred years after the Elizabethan settlement the battle raged round the compulsory use of the surplice and square cap, both being objected to by the extreme Calvinists or Puritans. This question was settled after 1662 by the secession of the Nonconformist clergy, and no more was heard of the matter until the "Oxford movement" in the 19th century. At the outset the followers of Newman and Pusey were more concerned with doctrine than with ritual; but it was natural that a reassertion of Catholic teaching should be followed by a revival of Catholic practice, and by the middle of the century certain "Ritualists," pleading the letter of the Ornaments Rubric in the Prayer Book, had revived the use of many of the pre-Reformation vestments. Into the history of the resulting controversies it is impossible to enter. Popular passion confused the issues, and raged as violently against the substitution of the surplice for the Geneva gown in the pulpit as against the revival of the "mass vestments." The law was invoked, and, confronted for the first time with the intricacies of the Ornaments Rubric, spoke with an uncertain voice. In 1870, however, the "vestments" were definitely pronounced illegal by the Privy Council (*Hebbert* v. *Purchas*), and since the "Ritualists" refused to bow to this decision, parliament intervened with the Public Worship Regulation Act of 1874, which set up a disciplinary machinery for enforcing the law, and at the same time reconstituted the Court of Arches (*q.v.*). The recalcitrant clergy refused to obey an act passed solely by the secular authority (convocation not having been consulted) or to acknowledge the jurisdiction of a court which had been robbed of its "spiritual" character. Prosecutions

[2] The term "Protestant" is used here in its widest sense of those Churches which reformed their doctrine and discipline as a result of the religious revolution of the 16th century (see REFORMATION).

"on the complaint of two parishioners" (too often qualified *ad hoc* by a temporary residence) followed; and since the act had provided no penalty save imprisonment for contempt of court, there followed the scandal of zealous clergymen being lodged in gaol indefinitely "for conscience' sake." This result revolted public opinion; the bishops acquired the habit (rendered easier by the personal expense involved in setting the law in motion) of vetoing, under the power given to them in the act, all prosecutions; and the act became a dead letter. The "persecution" had meanwhile produced its natural result: the use of the forbidden vestments rapidly spread; and since there was no central authority left competent to command obedience, every incumbent—intrenched in his freehold as a "corporation sole"—became a law unto himself. The outcome has been that in the Church of England, and in many of her daughter Churches, there exists a bewildering variety of "uses," varying from that of Sarum and that of Rome down to the closest possible approximation to the Geneva model.

Some explanation of this state of things may be ventured. Apart from those clergy (still the majority) who follow in all essentials the post-Reformation traditions of the English Church, there are three schools among those who justify the use of the ancient "eucharistic"[1] vestments: (1) a small number who affect to ignore the rules of the Prayer Book altogether, on the ground that no local or national Church has the right to alter the doctrines or practice of the Catholic Church, of which they are priests in virtue of their ordination, and whose prescriptions and usages they are in conscience bound to follow; (2) those who maintain that the Ornaments Rubric, in the phrase "second year of King Edward VI.," prescribes the ornaments in use *before* the first Prayer Book; (3) those who hold that under the Rubric the ornaments prescribed in the first Prayer Book are to be "had in use." The attitude of the first group needs no comment: it makes every priest the arbiter of what is or is not "Catholic," and is destructive of that principle of definite authority which is the very foundation of Catholicism. The attitude of the second group is based on a mistake as to the technical meaning of "the second year of Edward VI.," the second Prayer Book not having come into use till the third year.[2] As to the third group, their contention seems now to be admitted, though not all its implications. What, then, are the vestments sanctioned by the Ornaments Rubric? In its present form this dates from the Prayer Book revision of 1662. It runs: "And here it is to be noted that such ornaments of the church and of the ministers thereof at all times of their ministration shall be retained and be in use, as was in the Church of England by the authority of parliament in the second year of the reign of King Edward VI." The wording of this was taken from the last section of Elizabeth's Act of Uniformity, prefixed to the Prayer Book of 1559. In the Act, however, these words were added: "until other order shall be therein taken by the authority of the Queen's Majesty, with the advice of the Commissioners appointed and authorized under the Great Seal of England, for causes ecclesiastical, or of the Metropolitan." The Rubric in the Prayer Book of 1559 ran: ". . . the minister at the time of the Communion, and at all other times in his ministration, shall use, &c. . . . according to the Act of Parliament set in the beginning of this book."[3]

[1] This term is incorrect (save in the case of chasuble and maniple), but is that commonly employed by the "High Church" clergy.

[2] Edward VI. came to the throne on the 28th of January 1547; his "second year," therefore, lasted from the 28th of January 1548 to the 27th of January 1549. The first Prayer Book passed parliament on the 21st of January 1549, but did not receive the royal assent till later, probably March, and was not in *compulsory* use till Whitsunday, June 9th, 1549. The old rule, however, was that "every act of parliament in which the commencement thereof is not directed to be from a specific time, doth commence from the first day of the session of parliament in which such act is passed" (33 Geo. III. c. 13). The evidence is now clear that the Rubric refers to the first Prayer Book. This was decided in *Liddell* v. *Westerton* (1857), and is admitted in the Report of the five bishops to Convocation on *The Ornaments of the Church and its Ministers* (1908), which adduces conclusive evidence.

[3] This was inserted, probably by the Privy Council, as a memorandum or interpretation of the clause in the Act of Uniformity. Tomlinson (*The Prayer Book, Articles and Homilies*, p. 122 seq.) argues that this was a "fraud rubric" inserted without authority, and utterly perverting the meaning of the proviso in the Act of Uniformity. This argument is dealt with in the bishop's *Report*, p. 66.

Clearly it was the intention of the government, consistently with the whole trend of its policy, to cover its concession to the Protestant party dominant in the Commons by retaining some of the outward forms of the old services until such time as it should be expedient to "take other order." Then followed a period of great confusion. If the "massing vestments" continued anywhere in use, it was not for long. Whatever the letter of the law under the rubric, the Protestant bishops and the commissioners made short work of such "popish stuff" as chasubles, albs and the like. As for copes, in some places they were ordered to be worn, and were worn at the Holy Communion,[4] while elsewhere they were thrown into the bonfires with the rest.[5]

Fig. 8.—Anglican Priest in Cassock, Surplice, and Narrow Black Scarf. Brass of William Dye (d. 1567) at Westerham, Kent.

The difficulty seems to have been not to suppress the chasuble, of the use of which after 1559 not a single authoritative instance has been adduced, but to save the surplice, which the more zealous Puritans looked on with scarcely less disfavour. At last, in 1565, Queen Elizabeth determined to secure uniformity, and wrote to Archbishop Parker bidding him proceed by order, injunction or censure, "according to the order and appointment of such laws and ordinances as are provided by act of parliament, and the true meaning thereof, so that uniformity may be enforced." The result was the issue in 1566 by the archbishop of the statutory *Advertisements*, which fixed the vestments of the clergy as follows: (1) In the ministration of the Holy Communion in cathedral and collegiate churches, the principal minister to wear a cope, with gospeller and epistoler agreeably;[6] at all other prayers to be said at the Communion table, to use no copes but surplices; (2) the dean and prebendaries to wear surplice and hood; (3) every minister saying public prayers, or ministering the sacraments, to wear "a comely surplice with sleeves."

This has been decided by the judicial committee of the Privy Council (*Hebbert* v. *Purchas*, 1870; *Ridsdale* v. *Clifton*, 1877) to have been the "other order" contemplated in the Act of Uniformity of Elizabeth, and it was held that from this time the cope and surplice alone were legal vestments in the Church of England. The authority of the *Advertisements*, indeed, was and is disputed; but their lordships in their judgment pointed out that they were accepted as authoritative by the canons of 1603 (Can. 24 and 58), and argued convincingly that the revisers of the Prayer Book in 1662, in restoring the

[4] *Resolutions of 1561*, "Item that there be used only but one apparel; as the cope in the ministration of the Lord's Supper." See *Report*, p. 68.

[5] See Machyn's *Diary* (Camden Soc. 42; London, 1848), p. 208, for St Bartholomew's day, 1559: "All the roods, and Maries and Johns, and many other of the church goods, both copes, crosses, censers, altar cloths, rood cloths, books, banners, . . . with much other gear about London," were "burned with great wonder."

[6] Yet later the cope seems to have been authoritatively proscribed with the rest. In the *Acts of the Privy Council* (1578–1580), p. 208, is the following entry: "A letter to Sir Walter Ashton, Knight, Mr. Deane of Lichefield, etc. . . . touching certaine copes, vestments, tunicles and such other Popishe stuffe informed by letter from the Dean of Lichefield to be within the cathedral churche of Lichefield; they . . . are required to assemble themselves together in the towne of Lichefield and to cause the said Popishe stuffe to be sought out and brought before them, and thereupon to deface the same . . . and to see the same effectuallie done, and thereof to advertise their Lordships."

rubric of 1559, had no idea of legalizing any vestments other than those in customary use under the *Advertisements*, and the canons (cf. *Report* of sub-committee of Convocation, pp. 48, 49). The law, then, is perfectly clear, so far as two decisions of the highest court in the realm can make it so. But apart from the fact that the authority of the Privy Council, as not being a "spiritual" court, is denied by many of the clergy, no one claims that its decisions are irreversible in the light of fresh evidence.

Thirty years after the Ridsdale judgment, the ritual confusion in the Church of England was worse than ever, and the old ideal expressed in the Acts of Uniformity had given place to a desire to sanctify with some sort of authority the parochial "uses" which had grown up. In this respect the dominant opinion in the Church, intent on compromise, seems to have been expressed in the Report presented in 1908 to the convocation of the province of Canterbury by the sub-committee of five bishops appointed to investigate the matter, namely, that under the Ornaments Rubric the vestments prescribed in the first Prayer Book of Edward VI. are permitted, if not enjoined. Even if this be so, the question arises, what vestments were prescribed in the Prayer Book of 1549? It has been commonly assumed, and the assumption has been translated into practice, that the rubrics of 1549 prescribed the use of all the old "mass vestments." This, however, is not the case. In the short rubric before the communion service the celebrating priest is directed to "put upon him . . . a white alb plain with a vestment or cope," while the assisting priests or deacons are to wear "albs with tunicles." In the additional explanatory notes at the end of the book, after directions as to the wearing of surplice and hood in quire, in cathedral and collegiate churches (they are not made obligatory elsewhere), bishops are directed to wear, besides the rochet, a surplice or alb, and a cope or vestment, with a pastoral staff borne either by themselves or their chaplains.[1] Thus the alternative use of cope or chasuble (vestment) is allowed at the celebration of Holy Communion—an obvious compromise; of the amice, girdle (*cingulum*), maniple and stole there is not a word,[2] and the inference to be drawn is that these were now disused. The *cingulum*, indeed, which symbolized chastity (*i.e.* celibacy), would naturally have been discarded now that the clergy were allowed to marry, while the stole had become intimately associated with the doctrine of holy orders elaborated by the medieval schoolmen and rejected by the Reformers (see ORDER, HOLY). If this be so, the case is exactly parallel with that of the Lutheran Churches which, about the same time, had discarded all the "mass vestments" except the alb and chasuble. It becomes, then, a question whether the present-day practice of many of the clergy, ostensibly based on the rubric of 1549, is in fact covered by this. The revived use of the stole is the most curious problem involved; for this, originally due to a confusion of this vestment with the traditional Anglican black scarf, has now become all but universal among the clergy of all schools of thought (see STOLE).

The five bishops in their Report, tracing the various vestments to their origins, conclude that they are meaningless in themselves, and therefore things indifferent. This appears gravely to misread history. The chasuble and the rest, whatever their origin, had become associated during the middle ages with certain doctrines the rejection of which at the Reformation was symbolized by their disuse.[3] Their revival has proceeded *pari passu* with that of the doctrines with which they have long since become associated. With the truth or falsehood of these doctrines we are not here concerned; but that the revived vestments are chiefly valued because of their doctrinal significance the clergy who use them would be the last to deny. Nor is the argument that they are a visible manifestation of the continuity of the Church anything but a double-edged weapon; for, as Father Braun pertinently asks, if these be their symbolism, of what was their disuse in the Church of England for nigh on 300 years a symbol?[4]

In 1910 the question of the "permissive use of vestments," in connexion with that of the revision of the Prayer Book generally, was still under discussion in the convocations of the two provinces. But there was little chance that any change in the rubric, even in the improbable event of its receiving the sanction of parliament, would produce any appreciable effect. It is often forgotten that "extreme" ritual is no longer an "innovation" in the English Church; it has become the norm in a large number of parishes, and whole generations of Church people have grown up to whom it is the only familiar type of Christian worship. To attempt to "enforce the law" (whatever the law may be) would, therefore, seriously wound the consciences of a large number of people who are quite unconscious of having broken it. Formally to legalize the minimum enjoined by the rubrics of 1549 would, on the other hand, offend the "Protestant" section of the Church, without reconciling those who would be content with nothing short of the Catholic maximum.

AUTHORITIES.—All previous works on vestments have been largely superseded by Father Joseph Braun's *Die liturgische Gewandung* (Freiburg-im-Breisgau, 1907), a monument of careful and painstaking research, profusely illustrated. This contains a list of medieval writers on the subject, another of the inventories used by the author, and one of more modern works. W. B. Marriott's *Vestiarium Christianum* (1868), though it must now be read with caution, is still of much value, notably the second part, which gives texts (with translations) of passages bearing on the subject taken from early and medieval writers, with many interesting plates. Of other works may be mentioned Mgr. L. Duchesne's *Origines du culte chrétien* (Paris, 1903), and especially C. Rohault de Fleury's *La Messe* (Paris, 1883–89). See also F. X. Kraus, *Realencyklopädie der christlichen Altertümer* (Freiburg-i.-B., 1882, 1886); Smith and Cheetham, *Dict. of Christian Antiquities* (ed. 1893) and *The Catholic Encyclopaedia* (New York, 1907 onwards).

For the vestment question in the Church of England see the Report of the sub-committee of Convocation on *The Ornaments of the Church and its Ministers* (1908); *Hierurgia Anglicana*, documents and extracts illustrative of the ceremonial of the Anglican Church after the Reformation, new ed. revised and enlarged by Vernon Staley (1902–3); J. T. Tomlinson, *The Prayer Book, Articles and Homilies* (1897), a polemical work from the Protestant point of view, but scholarly and based on a mass of contemporary authorities to which references are given; the bishop of Exeter, *The Ornaments Rubric* (London, 1901), a pamphlet. For the legal aspect of the question see G. J. Talbot, *Modern Decisions on Ritual* (London, 1894). (W. A. P.)

[1] There is no mention of mitre, gloves, dalmatic, tunicle, sandals and caligae, which were presumably discontinued.

[2] It has been argued that the term "vestment" covers all these. The *Report* of 1908 (Appendix A, p. 109) says cautiously that the word "may perhaps in some cases stand for the chasuble with the amice, stole and fanon, the alb being mentioned separately," but adds that "very many of the instances commonly cited for this (*e.g.* those in *Essays on Ceremonial*, p. 246) are quite inconclusive, as 'vestment' is often a convertible term with 'chasuble'; and it does not seem to be at all conclusively established that 'vestment' with 'alb' mentioned separately, and 'cope' given as an alternative, in a document with the precision and directive force of a Rubric, means more than the actual chasuble." Father Braun (*Die liturg. Gewandung in der Englischen Staatskirche*) endorses this opinion. He gives reasons for believing that in the Church of England, under the first Prayer Book, as in the Lutheran Churches, while chasuble and alb were retained, stole, maniple, amice and girdle were discontinued. With this the bishop of Exeter (*Ornaments Rubric*, p. 30) would seem to agree, when he says that "the customs of the present day do not fully accord with any reasonable interpretation of the rubric. The stole, now nearly universal, is only covered by the rubric if the word 'vestment' be taken to include it (a very dubious point), and then only at Holy Communion."

[3] This is also the view taken by Father J. Braun, S.J., in his paper on liturgical dress in the Church of England, contributed to *Stimmen aus Maria-Laach* (1910, Heft 7, Freiburg-im-Breisgau). In this he criticizes the bishops' Report in a sympathetic spirit, but points out how intimately the symbolism of the vestments had become associated with the doctrine of the Sacrifice of the Mass, and how logical was the action of the Reformers in rejecting certain of these vestments.

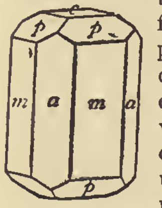
[4] He sees in the revival of "vestments" "an energetic condemnation of the English Reformation." He adds that this is, of course, unintentional (*allerdings ohne das sein zu wollen*). A more intimate acquaintance with the language commonly used by many of the more extreme "Ritualists" would have shown him that there has been, and is, no lack of such intention.

VESTRIS, GAETANO APPOLINO BALDASSARE (1729–1808), French ballet dancer, was born in Florence and made his *début* at the Opéra in 1748. By 1751 his success and his vanity had grown to such a point that he is reported to have said, "There are but three great men in Europe—the king of Prussia, Voltaire and I." He was an excellent mimic as well as dancer. From 1770 to 1776 he was master and composer of ballets, retiring, in favour of Noverre, with a pension. Two other pensions fell to him, when he gave up his positions of first dancer and of first dancer of court ballets, amounting in all to 9200 livres. Vestris married a dancer, Anna Heinel (1752–1808), of German origin, who had a wonderful success at the Opéra. He reappeared at the age of sixty-one on the occasion of his grandson's *début*. By the dancer Mlle. Allard, Vestris had a son, Marie Auguste Vestris Allard (1760–1842), also a ballet dancer, who surpassed his father, if possible, in both talent and vanity. His son, Auguste Armand Vestris (b. 1825), who took to the same profession, made his *début* at the Opéra in 1800, but left Paris for Italy and never reappeared in France. Gaetano's brother, Angelo Vestris (1730–1809), married Marie Rose Gourgaud, the sister of the actor Dugazon (*q.v.*).

VESTRIS, LUCIA ELIZABETH (1797–1856), English actress, was born in London in January 1797, the daughter of Gaetano Stefano Bartolozzi (1757–1821) and granddaughter of Francesco Bartolozzi, the engraver. In 1813 she married Auguste Armand Vestris (see above), who deserted her four years later. With an agreeable contralto voice and a pleasing face and figure, Madame Vestris had made her first appearance in Italian opera in the title-rôle of Peter Winter's *Il ratto di Proserpina* at the King's Theatre in 1815. She had an immediate success in both London and Paris, where she played Camille to Talma's Horace in *Horace*. Her first hit in English was at Drury Lane in James Cobb's (1756–1818) *Siege of Belgrade* (1820). She was particularly a favourite in "breeches parts," like Cherubino in the *Marriage of Figaro*, and in *Don Giovanni*, and with such introduced songs as "Cherry Ripe," "Meet me by moonlight alone," "I've been roaming," etc. In 1831, having accumulated a fortune, she became lessee of the Olympic Theatre, and began the presentation of a series of burlesques and extravaganzas for which she made this house famous. She married Charles James Mathews in 1838, accompanying him to America and aiding him in his subsequent managerial ventures. Her last appearance (1854) was for his benefit in an adaptation of Madame de Girardin's *La Joie fait peur*, called *Sunshine through Clouds*, and she died in London on the 8th of August 1856. Her musical accomplishments and education were not sufficient to distinguish her in grand opera, and in high comedy she was only moderately successful. But in plays like *Loan of a Lover, Paul Pry, Naval Engagements*, etc., she was delightfully arch and bewitching.

VESTRY (O. Fr. *vestiaire*, Lat. *vestiarium*, a wardrobe), a place or room adjoining a church, where the vestments of the minister are kept. Hence the name applied to an assembly of the parishioners, usually convened in the vestry, to transact the business of the parish. In populous parishes it obtains by custom in some, and by the "Adoptive" Vestries Act 1831 in others, to choose yearly a select number of parishioners, called a "select vestry," to manage the concerns of the parish. (See PARISH.)

VESUVIANITE, a rock-forming mineral of complex composition. It is a basic calcium and aluminium silicate containing small amounts of iron, magnesium, water, fluorine, etc., and sometimes boron; the approximate formula is $H_2Ca_6(Al,Fe)_3Si_5O_{18}$. It crystallizes in the tetragonal system, but often exhibits optical anomalies, and the optical sign varies from positive to negative. Well-developed crystals are of frequent occurrence. They usually have the form of four- or eight-sided prisms terminated by the basal planes (*c*) and pyramid-planes (*p* in fig.); the prism-planes are vertically striated and the basal planes smooth and bright. Crystals are transparent to translucent, vitreous in lustre and vary in colour from brown to green; a sky-blue variety, called *cyprine*, owes its colour to the presence of a trace of copper. The specific gravity is 3·4 and the hardness 6½. The name vesuvianite was given by A. G. Werner in 1795, because fine crystals of the mineral are found at Vesuvius; these are brown in colour and occur in the ejected limestone blocks of Monte Somma. Several other names have been applied to this species, one of which, *idocrase* of R. J. Haüy (1796), is now in common use.



Vesuvianite is typically a mineral of contact-metamorphic origin, occurring most frequently in crystalline limestones at their contact with igneous rock-masses; it also occurs in serpentine, chlorite-schist and gneiss, and is usually associated with garnet, diopside, wollastonite, &c. Localities which have yielded fine crystallized specimens are the Ala valley near Turin, Piedmont, Monte Somma (Vesuvius), Monzoni in the Fassa valley, Tirol, Achmatovsk near Zlatonst in the Urals, the River Wilui district near Lake Baikal in Siberia ("wiluite"), Christiansand in Norway, &c. When found in transparent crystals of a good green or brown colour it is occasionally cut as a gem-stone. A compact variety, closely resembling jade in appearance, has been used as an ornamental stone. (L. J. S.)

VESUVIUS (also *Vesevus* in ancient poets), a volcano rising from the eastern margin of the Bay of Naples in Italy, about 7 m. E.S.E. of Naples, in the midst of a region which has been densely populated by a civilized community for more than twenty-five centuries. Hence the mountain has served as a type for the general popular conception of a volcano, and its history has supplied a large part of the information on which geological theories of volcanic action have been based. The height of the mountain varies from time to time within limits of several hundred feet, according to the effects of successive eruptions, but averages about 4000 ft. above sea-level (in June 1900, 4275 ft., but after the eruption of 1906 considerably less). Vesuvius consists of two distinct portions. On the northern side a lofty semicircular cliff, reaching a height of 3714 ft., half encircles the present active cone, and descends in long slopes towards the plains below. This precipice, known as Monte Somma, forms the wall of an ancient prehistoric crater of vastly greater size than that of the present volcano. The continuation of the same wall round its southern half has been in great measure obliterated by the operations of the modern vent, which has built a younger cone upon it, and is gradually filling up the hollow of the prehistoric crater. At the time of its greatest dimensions the volcano was perhaps twice as high as it is now. By a colossal eruption, of which no historical record remains, the upper half of the cone was blown away. It was around this truncated cone that the early Greek settlers founded their little colonies.

At the beginning of the Christian era, and for many previous centuries, no eruption had been known to take place from the mountain, and the volcanic nature of the locality was perhaps not even suspected by the inhabitants who planted their vineyards along its fertile slopes, and built their numerous villages and towns around its base. The geographer Strabo, however, detected the probable volcanic origin of the cone and drew attention to its cindery and evidently fire-eaten rocks. From his account and other references in classical authors we gather that in the first century of the Christian era, and probably for hundreds of years before that time, the sides of the mountain were richly cultivated, as they are still, the vineyards being of extraordinary fertility. The wine they produce is known as *Lacrimae Christi*. But towards the top the upward growth of vegetation had not concealed the loose ashes which still remained as evidence of the volcanic nature of the place. On this barren summit lay a wide flat depression, surrounded with rugged walls of rock, which were festooned with wild vines. The present crater-wall of Monte Somma is doubtless a relic of that time. It was in this lofty rock-girt hollow that the gladiator Spartacus was besieged by the praetor Claudius Pulcher; he escaped by twisting ropes of vine branches and descending through unguarded fissures in the crater-rim. A painting found in Pompeii in 1879 represents Vesuvius before the eruption (*Notizie degli scavi*, 1880, pl. vii.).

After centuries of quiescence the volcanic energy began again to manifest itself in a succession of earthquakes, which spread alarm through Campania. For some sixteen years after 63 these convulsions continued, doing much damage to the surrounding towns. At Pompeii, for example, among other devastation, the temple of Isis was shaken into ruins, and, as an inscription records, it was rebuilt from the foundations by the munificence of a private citizen. On the 24th of August 79 the earthquakes, which had been growing more violent, culminated in a tremendous explosion of Vesuvius. A contemporary account of this event has been preserved in two letters of the younger Pliny to the historian Tacitus. He was staying at Misenum with his uncle, the elder Pliny, who was in command of the fleet. The latter set out on the afternoon of the 24th to attempt to rescue people at Herculaneum, but came too late, and went to Stabiae, where he spent the night, and died the following morning, suffocated by the poisonous fumes which were exhaled from the earth. This eruption was attended with great destruction of life and property. Three towns are known to have been destroyed—Herculaneum at the western base of the volcano, Pompeii on the south-east side, and Stabiae, still farther south, on the site of the modern Castellamare. There is no evidence that any lava was emitted during this eruption. But the abundant steam given off by the volcano seems to have condensed into copious rain, which, mixing with the light volcanic dust and ash, gave rise to torrents of pasty mud, that flowed down the slopes and overwhelmed houses and villages. Herculaneum is believed to have been destroyed by these "water lavas," and there is reason to suppose that similar materials filled the cellars and lower parts of Pompeii. Comparing the statements of Pliny with the facts still observable in the district, we perceive that this first recorded eruption of Vesuvius belongs to that phase of volcanic action known as the *paroxysmal*, when, after a longer or shorter period of comparative tranquillity, a volcano rapidly resumes its energy and the partially filled-up crater is cleared out by a succession of tremendous explosions.

For nearly fifteen hundred years after the catastrophe of 79 Vesuvius remained in a condition of less activity. Occasional eruptions are mentioned, *e.g.* in A.D. 203, 472 and 685, and nine in the middle ages down to 1500. None, however, was of equal importance with the first, and their details are given vaguely by the authors who allude to them. By the end of the 15th century the mountain had resumed much the same general aspect as it presented before the eruption described by Pliny. Its crater-walls, some 5 m. in circumference, were hung with trees and brushwood, and at their base stretched a wide grassy plain, where cattle grazed and the wild boar lurked in the thickets. The central tract was a lower plain, covered with loose ashes and marked by a few pools of hot and saline water. At length, after a series of earthquakes lasting for six months and gradually increasing in violence, the volcano burst into renewed paroxysmal activity on the 16th of December 1631. Vast clouds of dust and stones, blown out of the crater and funnel of the volcano, were hurled into the air and carried for hundreds of miles, the finer particles falling to the earth even in the Adriatic and at Constantinople. The clouds of steam condensed into copious torrents, which, mingling with the fine ashes, produced muddy streams that swept far and wide over the plains, reaching even to the foot of the Apennines. Issuing from the flanks of the mountain, several streams of lava flowed down towards the west and south, and reached the sea at twelve or thirteen different points. Though the inhabitants had been warned by the earlier convulsions of the mountain, so swiftly did destruction come upon them that 18,000 are said to have lost their lives.

Since this great convulsion, which emptied the crater, Vesuvius has never again relapsed into a condition of total quiescence. At intervals, varying from a few weeks or months to a few years, it has broken out into eruption, sometimes emitting only steam, dust and scoriae, but frequently also streams of lava. The years 1766–67, 1779, 1794, 1822, 1872 and 1906 were marked by special activity. The last completely altered the aspect of the cone, considerably reducing its height.

The modern cone of the mountain has been built up by successive discharges of lava and fragmentary materials round a vent of eruption, which lies a little south of the centre of the prehistoric crater. The southern segment of the ancient cone, answering to the semicircular wall of Somma on the north side, has been almost concealed, but is still traceable among the younger accumulations. The numerous deep ravines which indented the sides of the prehistoric volcano, and still form a marked feature on the outer slopes of Somma, have on the south side served as channels to guide the currents of lava from the younger cone. But they are gradually being filled up there and will ultimately disappear under the sheets of molten rock that from time to time rush into them from above. On one of the ridges between these radiating valleys an observatory for watching the progress of the volcano was established by the Neapolitan government, and is still supported as a national institution. A continuous record of each phase in the volcanic changes has been taken, and some progress has been made in the study of the phenomena of Vesuvius, and in prognosticating the occurrence and probable intensity of eruptions. The foot of the cone is reached from Naples by electric railway, and thence a wire-rope railway (opened in 1880) carries visitors to within 150 yds. of the mouth of the crater.
